One of the factors which has, I believe, played a most prominent part in the production of complications and mortality in these procedures has been the type of anesthesia. We began our total and subtotal gastrectomies using ether anesthesia, but its disadvantages soon became obvious. These gastrectomies involve so many technical steps in the upper part of the abdomen and in such deep cavities that a situation most undesirable for ether anesthesia arises. Patients who are poor risks, often in advanced years, must for adequate relaxation be kept under deep ether anesthesia too long, and it soon became evident that deep anesthesia over such periods was followed by profound shock. We therefore next undertook subtotal gastrectomy under ethylene anesthesia, given through an intratracheal catheter, plus regional infiltration with Metycain in the abdominal wall. Under this plan a considerable number of subtotal and a few total gastrectomies were accomplished with fairly satisfactory relaxation, but still with considerable degrees of shock. When splanchnic anesthesia was added to intratracheal ethylene and regional anesthesia, there was more adequate relaxation and less of a drop in blood pressure. Because inhalation anesthesia in general provides a degree of relaxation inadequate to facilitate high gastric resections, we turned to spinal anesthesia, employing novocain, Spinocain and Metycain. The disadvantage of this type of anesthesia was the limited length of time on which one could count for complete relaxation, it was often limited to an hour or an hour and a half, and rarely extended over an hour and three quarters. This kind of anesthesia was distinctly undesirable for patients undergoing total or subtotal gastrectomy. When patients who had been under spinal anesthesia for an hour or an hour and a half and who had already undergone a certain number of manipulative procedures in the upper part of the abdomen that are so well calculated to produce shock came out of their spinal anesthesia and required a deep general anesthesia to produce relaxation sufficient to complete the technical procedures deep in the upper abdomen, the result was often a severe degree of shock, which in many cases no doubt resulted ultimately in fatalities, or in pulmonary complications that ultimately brought them about.

Satisfactory anesthesia for patients submitted to subtotal and total gastrectomies was not obtained until dilute nupercain spinal anesthesia became

available. When we first began to employ nupercain spinal anesthesia, although it produced the desired length of anesthesia, it likewise caused unfavorable complications and even fatalities. It was not until W. Howard Jones,<sup>1</sup> of London, proposed the employment of a dilute solution, 1:1500, that these objectionable features were eliminated. By the employment of a 1:1500 solution, in doses up to 20 cc in proportion to the height of the individual, satisfactory high spinal anesthesia for total and subtotal gastrectomy is now secured. Complete motor relaxation is sustained for two and a half to three hours, with even less of a drop in blood pressure than occurs with the spinal anesthetics in which novocain is employed. There has not infrequently been an earlier loss of sensory anesthesia than of motor anesthesia, but this condition can be cared for by the light administration of a supplementary anesthetic. There has been nothing in our experience—which has so far embraced more than 300 cases—that has played a greater part in lowering the mortality and complications in subtotal and total gastrectomies than has this type of spinal anesthesia.

Since we have employed all the different types of operative procedures for partial gastrectomy, it will be of value to present the reasons why we have given up some of them, and to demonstrate the type of procedure which we have employed for several years. We do so not because we believe it to be the one which should be universally employed, but because it represents, at least in our hands, the ultimate procedure arrived at after a considerable experience with other methods and their gradual elimination.

As a result of our experience with the Billroth I operation we are convinced that it is the *safest* of all methods of performing subtotal gastrectomy. This is due to the fact that the operation is conducted above the transverse colon, with the omentum covering the small intestine, without any great disturbance of the abdominal contents, and thus with less danger of general peritoneal contamination. With the direct anastomosis between the open end of the duodenum and the cut end of the stomach, this type of subtotal gastrectomy results in prompt drainage and little gastric stasis. The operation is followed by less shock and less danger of peritonitis than is any other procedure by which subtotal gastrectomy is accomplished. Its disadvantage, particularly in relation to the surgical treatment of ulcer, is that, since one must approximate the cut end of the duodenum and the cut end of the stomach, there is a constant tendency to remove inadequate amounts of stomach wall in order to facilitate approximation of the two structures, and thus not to accomplish the low post-

operative values for gastric acidity which are associated with high gastric resections. Furthermore, there have been recurrent ulcers in the new suture line in the Billroth I type of resection requiring reoperation and higher resection, and there has likewise been contraction of the anastomoses between the duodenum and the stomach. Except in bad-risk patients with local prepyloric malignant lesions we have largely abandoned the Billroth I procedure.

We have entirely eliminated the Billroth II type of subtotal gastrectomy, since it is impossible to make a satisfactory gastroenterostomy of the type called for by this operation when a sufficiently high subtotal gastrectomy is done.

For a number of years we employed the Reichel-Polya type of subtotal gastrectomy, but gave it up several years ago in favor of the Hofmeister antecolic type. Our reason was that an anastomosis between the jejunum and the entire open end of the stomach offers a greater chance of leakage than does one between a third of the open end of the stomach and the jejunum. In addition, post-operative roentgenograms have satisfied us that when two thirds of the cut end of the stomach is closed and the remaining third is anastomosed end-to-side to the jejunum, a better functioning stoma results, with a proper retention of food in the stomach over a longer period.

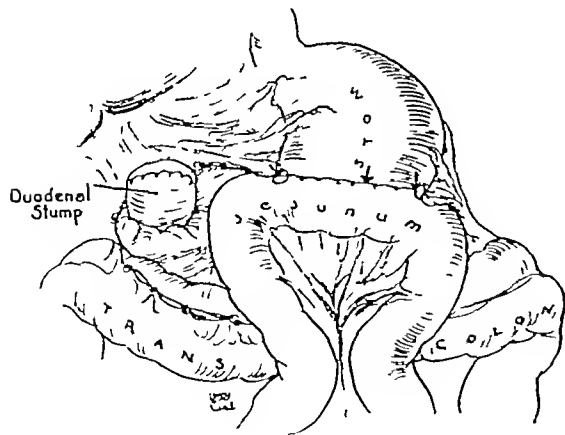

Figure 1

*This line drawing shows the antecolic Hofmeister type of anastomosis which we have now employed for several years. In this illustration the anastomotic opening into the stomach is between the arrows, the remaining cut end of the stomach being closed and the jejunum buttressed over it.*

The plan of operative procedure which we at present employ consists of the removal without stomach clamps of from three fourths to four fifths of the stomach, its transection by cautery between clips inserted by the von Petz sewing ma-

chine, the closure of the upper two thirds of the cut end of the stomach, and the anastomosis of a long loop of jejunum brought up over the transverse colon to the lower third of the cut end, the upper end of the jejunum being buttressed over the closed upper two thirds to reinforce it (Figs 1 and 2).

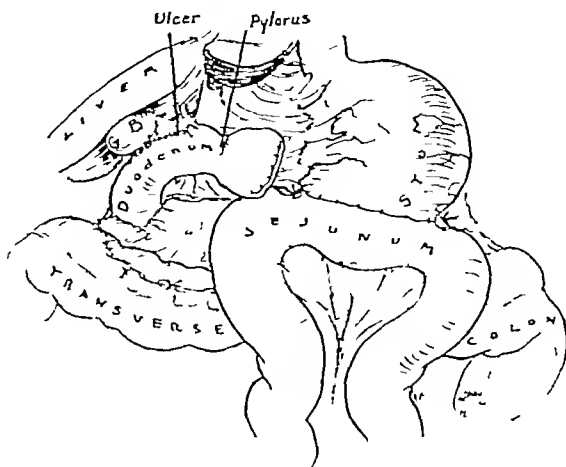

Figure 2.

*This illustrates the operation of resection and exclusion, as proposed by Finsterer. It is the same type of gastric resection (Hofmeister) as shown in Figure 1 but the duodenum with its contained low and adherent ulcer is left in place together with a small section of the prepyloric region of the stomach. In patients with badly adherent ulcers situated low on the duodenum and close to the entrance of the common duct into the duodenum this has been a valuable and mortality-diminishing type of operation.*

In the beginning, many of our anastomoses were made retrocolic in position. This procedure was given up because of the number of obstructions which occurred when the jejunum was brought through a rent in the mesentery of the transverse colon.

When we first employed antecolic Hofmeister anastomosis, enteroenterostomy was always done. This has been eliminated, for two reasons: because satisfactory function is obtained without it and an additional technical step, time-consuming in character and with the added risk of leakage, is avoided, and because in subtotal gastrectomy for ulcer it is physiologically undesirable. Subtotal gastrectomy for peptic ulcer is successful in proportion to its ability permanently to lower gastric acidity. It accomplishes this by the amount of stomach removed, thus eliminating a high fraction of the acid-bearing glands in the stomach wall, and by the return to the stomach from the jejunum of alkaline jejunal contents, which in turn lower gastric acidity by neutralizing the acids in the remaining gastric stump. When,

therefore, jejunojejunostomy is done between the proximal and distal loops of the jejunum anastomosed to the stomach, a large portion of the alkaline jejunal contents is thus sidetracked into the jejunum below the stomach, and does not return to the stomach to accomplish acid neutralization. For the last six years no enteroenterostomies have been performed in subtotal gastrectomies, and in but 1 case has there been an obstruction in the antecolic loop which required secondary operation and enteroenterostomy. In this case, I am convinced as a result of further experience that had I

nourishment required for normal activity. Technically, total gastrectomy has been made very much easier by gently wiping out that portion of the esophagus which runs through the diaphragm, thus obtaining 10 or 12 extra centimeters of esophagus, this permits anastomosis between the jejunum and the cut end of the esophagus to be made much nearer the abdominal wall and with much more adequate exposure than when it is made directly at the level of the diaphragm. We<sup>2</sup> have recently published our technical experiences with this operation, so that it is unnecessary to describe these

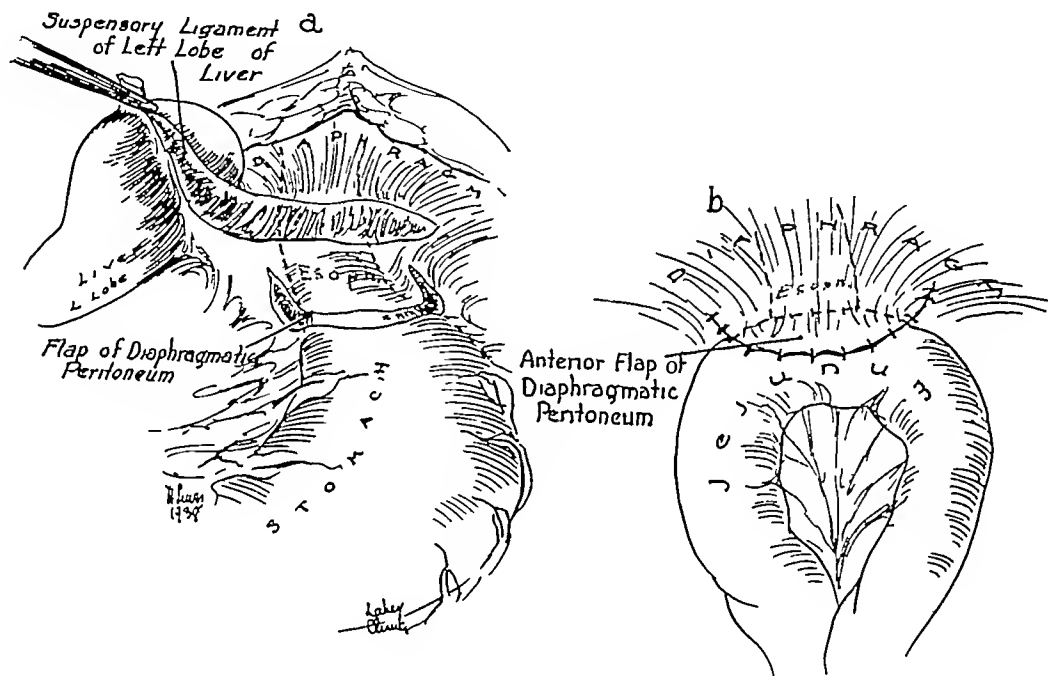

Figure 3 Total Gastrectomy

- a. This shows the anterior peritoneal apron cut from the peritoneal covering of the diaphragm and cardia, which is sutured to the jejunum below the line of anastomosis, thus removing traction on the line of suture between the jejunum and the esophagus. A similar flap is cut from the back flap is similarly sutured.
- b. In this drawing the anterior peritoneal flap has been sutured to the jejunum. The posterior

been patient for a few days longer enteroenterostomy might also have proved unnecessary. Even in the last 4 total gastrectomies in which the end of the esophagus was sutured to the side of the jejunum, no enteroenterostomies have been done with the purpose of converting the proximal loop of jejunum into a semblance of a stomach in which food is retained over a considerable period of time.

Total gastrectomy has been performed in our clinic in 9 cases, in 5 of these it has been surgically successful, and the procedure has been demonstrated by a number of surgeons as technically feasible, leaving the patients in such a condition that they are able to eat enough food to gain the

steps in detail. One step, however, which is probably obvious to everyone experienced with total gastrectomy, is the fashioning of flaps of peritoneum from the diaphragm, to be attached to the jejunum below its anastomosis to the esophagus, so that its weight at that point will be removed from the suture line and be taken up by the flaps (Fig 3).

One of the postoperative complications which is most disturbing, particularly with subtotal gastrectomy, is that of failure of the anastomosed jejunum to drain the stomach. With increasing experience with this operation we have become more and more patient in waiting for these anastomoses to open. Recently a patient with high subtotal gastrectomy went for fifteen days without an

emptying of the stomach, only to have the anastomosis open completely on the sixteenth day and drain most satisfactorily from then on. It is by no means easy not to reoperate on patients in whom gastric emptying is delayed, but we are convinced from our and others' experiences that secondary operation may often be avoided if one will be patient for the anastomotic opening to establish itself.

In our earlier cases one of the most disturbing features of subtotal gastrectomy was the wound complications. Three factors, I feel sure, have played an important part in diminishing them. The first is the employment of a cellophane pad to protect wound edges, in which a strip of cellophane is sewed between two layers of gauze.<sup>3</sup> The second is the carrying out of a suggestion which I<sup>4</sup> made some years ago, to the effect that all patients with carcinoma of the stomach should be prepared for operation by repeated lavages with hydrochloric acid. An investigation in the clinic, soon to be published, demonstrates that by this means, even in cases of carcinoma of the stomach where there is no gastric acidity and a high bacterial count, the gastric contents may be made practically free of organisms. Finally, one of the most important factors having to do with the diminution of wound infection is the elimination of layer catgut sutures. Three or four years ago I began closing all abdominal wounds of patients submitted to subtotal gastrectomy with through-and-through mass silk sutures. This was soon modified so that the peritoneum was closed with a continuous locked chromic catgut suture and the remainder of the abdominal wall closed solely with through-and-through mass silk sutures, passing through skin, subcutaneous fat, fascia and muscle, but not through the peritoneum. This has been a very satisfactory method. There have been fewer evertations, and there has been a marked saving of time, particularly desirable at the end of the operation when patient and surgeon have frequently already been subjected to a severe ordeal.

#### CONCLUSIONS

Subtotal and total gastrectomies for ulcer and cancer are being and will be, we believe, more frequently done than they have been in the past.

A considerable experience with all types of anesthesia in gastrectomy leads us to believe that dilute nupercain spinal anesthesia, 1:1500 dilution, using not more than 20 cc., provides as desirable a length of anesthesia, with as little shock, as can be obtained by any other type of anesthesia.

After varied experience with all the types of gastric resection, we are convinced that the Hofmeister type of subtotal gastrectomy, with antecolic anastomosis, is the most satisfactory

Enteroenterostomy is not only unnecessary but undesirable.

Wound complications play a considerable part in the mortality of subtotal gastrectomy. They are materially lessened, we believe, by protecting all the wound edges with cellophane pads, by sterilizing the gastric contents—when the acidity is low or absent—by lavage with hydrochloric acid, and by the employment of a single layer of chromic catgut in suturing the peritoneum, with mass silk sutures for the remainder of the abdominal wall.

#### DISCUSSION

DR. CHARLES P CHANDLER, Montpelier, Vermont. As I have had no personal experience with either subtotal or total gastrectomy, my discussion must consist of a review of the available literature in relation to this subject. As the choice of the operation in each individual case apparently depends on the inclination of the surgeon, I shall confine myself to the reports from these operations as regards the operative mortality and postoperative morbidity.

The most pessimistic report appears in Babcock's textbook, where it is stated that when total gastrectomy is done for carcinoma of the stomach recurrence is inevitable and the patient has but one or two years of postoperative life, and that no permanent recovery has been recorded. This is evidently a misstatement, for I found that a large number of cases had been reported, some long before 1928, in which the postoperative life was five years or longer, furthermore, many of the patients died of causes other than recurrence. The most optimistic statement I found was in the closing paragraph of a paper written by Clute and Albright. This states: "From the standpoint of restoring health to the patient for a period of several months or years, the results of this operation are decidedly favorable. The patients have good appetite, they enjoy eating, and the disturbances subsequent to the operation may be controlled sufficiently to avoid discomfort. Some patients are able to resume their occupations and lead active lives." Between these extremes, a variety of results are reported.

The operation has apparently been done with much greater frequency in Europe than in the United States. Finsterer is reported to have performed it more than 2000 times with a mortality of 3 or 4 per cent in ulcer cases and 24 or 30 per cent in cancer cases. Veribily, in Budapest, has done 2400 resections, with a combined mortality in benign and malignant lesions of 7.8 per cent. No such series has been reported by an American surgeon.

The operative mortality in the cancer cases throughout America varies between 14 and 50 per cent, where the immediate cause of death was given it was attributed in the majority of cases to peritonitis resulting from leakage at the esophageal anastomosis. In the case reports there is a marked similarity in results. For example, Finney mentions 110 cases, all but 4 of which were shown to be carcinoma by pathological examination. Sixty-six patients recovered from the operation, but most of them survived for comparatively short periods, the longest being six years. Allen reported 16 cases, in 8 of which the patient

survived the operation. Five are still living, 2 had recurrences, 1, an ulcer case, was not traced, 2 are living and well, at fourteen months and four and a half years respectively. Of the many cases reviewed where long survival is mentioned—that is, a period of four years or more—there seemed to be a certain reticence as to the exact condition of the patient. I found, however, that in a number of these cases there developed a condition similar to pernicious anemia, and in some a true pernicious anemia, 1 such case being recorded at the Mayo Clinic in which the patient survived for three years. Allen attributes this condition to the fact that these patients do not eat meat. Merklen and Froehlich made a study of the blood of 28 gastrectomized patients, and concluded that gastrectomy does not cause pernicious or any other kind of anemia. They cited several reported cases of pernicious and other anemias which occurred in gastrectomized patients, but they considered these incidental and not due to the gastrectomy.

As a basis for a satisfactory result, I suggest the following: that the patient be able to regain, at least partially, the position he previously occupied in his community, that he give pleasure to his relatives and friends rather than be a care and that he derive enough enjoyment from life to make existence bearable. Practically none of the many case reports included any such information. In fact, a few left one with the impression that the lives of the patients had been prolonged not so much for their benefit as to demonstrate a feat of surgery.

Warwick reported autopsies on 176 patients who died of carcinoma of the stomach. Of these cases no metastasis was demonstrable in 23 per cent. This clearly indicates that many cases with a possibility of cure are overlooked. At present, with our improved methods of examination and diagnosis, such cases will be given the benefit of operation, with continued improvement along these lines we may hope for much earlier diagnoses, and the associated advance in technic will bring more favorable results. Thus far, at least, radical surgery offers the only known hope for the successful treatment of carcinoma of the stomach.

DR PEIRCE H. LEAVITT, Brockton, Massachusetts. I was very much impressed by the large number of patients with ulcer who have appeared at Dr. Lahey's clinic. There were so many that I suspect that surgeons like myself, practicing in much smaller cities than Boston, see very few cases in comparison, in fact not enough to warrant our doing gastrectomies. I believe that such cases should be left to specialists in this brand of surgery. The man who sees them only occasionally should not attempt to treat them, and if I myself had an ulcer of the stomach I should want it treated by someone who had cared for a great number of cases of this type.

I compliment Dr. Lahey on his excellent development of the operation, and the marked decrease in mortality he has been able to show.

DR EDWARD R. LAMPSON, Hartford, Connecticut. When Dr. Lahey published several years ago an article on subtotal gastrectomy for duodenal ulcer he reported a mortality of 18.5 per cent, as I remember it. He showed a great deal of courage in presenting a mortality of that degree. He then reported 47 cases with a 10 per cent mortality, he has now done nearly 50 consecutive cases with no deaths. This shows that he was absolutely justified in continuing the method that he finally adopted.

While in England a year ago I spent my afternoons visiting the London hospitals, where I found that they were largely employing the method of subtotal gastrectomy in their cases of gastric and duodenal ulcer. At the Mid-

dlesex Hospital I saw one very able surgeon do two such operations in one afternoon. One of his assistants told me that their mortality was about 2 per cent, that they had handled 32 consecutive cases without a death, and that they generally did an antecolic anastomosis and found it unnecessary to follow it with an enteroenterostomy.

Notwithstanding Dr. Lahey's statements and the opinions of many other surgeons in regard to the advantages of gastrectomy, I think that there is still a use for gastroenterostomy in certain types of cases and under certain conditions.

There is one question that I should like to ask Dr. Lahey. Do you do an antiperistaltic or an isoperistaltic union of the intestine to the stomach?

DR DAVID W. PARKER, Manchester, New Hampshire. A certain percentage of the ulcer cases are particularly annoying and distressing, namely those which have recurrent massive hemorrhage. I should like to have Dr. Lahey elaborate a little on his impressions of that group.

DR LAHEY. I realize that the subject of ulcer invites endless discussion. I meant particularly to present here our actual experiences with the technical side of this problem, because we have had such a bad time with it. Perhaps we have not been so apt as we should have been in reducing the mortality, but at any rate it was most distressing before the last year and a half to hear other surgeons speak of a mortality rate in subtotal gastrectomy of 2 per cent when we were unable to achieve it. We had been able to standardize nearly all the other major surgical procedures which we had undertaken on colons, rectums, diverticula and thyroids, and various other operations, but it seemed almost hopeless to reduce the mortality in subtotal gastrectomy. When I recall what made these operations difficult, I am convinced that there are definite factors which have brought the high mortality rate down to zero. I present these deductions not in a boastful spirit, but because they may be helpful. Nor do I mean to imply that my suggestions represent anything more than our own deductions. It is quite probable that other surgeons would have or have accomplished as great improvements in their mortality rates by methods different from ours.

As to isoperistaltic versus antiperistaltic anastomosis, I do not believe it matters which is selected. The stomach and intestine are joined in the way they fit best.

I do not wish to take up too much time discussing technical steps, but having done a subtotal gastrectomy for many of you yesterday morning, it seems to me that it may be of value to repeat some of the things I said then. When one does a high gastric resection, and has pulled the stump of the stomach well down out of the left hypochondrium, one tends to forget that when it is released it will retract high up. For that reason, doing antecolic anastomoses as we do, it is necessary to employ long loops of jejunum lest when the stomach retracts there is tension on the suture line.

Another important point which I stressed yesterday morning was that, when the jejunum is anastomosed to the end of the stomach, the suture should be started near one mesenteric border. If done in this way, one finds, when the anastomosis is complete, that a sufficient portion of the lumen remains free. Another mistake which has undoubtedly been frequently made is to run the anastomosis of the jejunum to the stomach obliquely across the jejunum instead of exactly parallel with the mesentery, thus causing twists in the jejunum which do not drain well. These are technical mistakes, but they represent features which tend to create postoperative difficulties in this operation.

As regards hemorrhage, this is an extremely difficult subject to discuss because it opens up such a large field of possibilities. One should, however, recall our experience with hemorrhage, that is, that of all our patients having one hemorrhage, 40 per cent failed under medical treatment, and of all those having two or more hemorrhages, 80 per cent failed. It should be realized that there are two types of bleeding, the mild chronic and the serious progressive, in the latter of which everyone today admits that something radical must be done. This is a state which requires the keenest clinical judgment, since the decision to operate must be deferred until it is certain that the hemorrhage will be serious. Of course under these conditions it is possible either to wait too long or to operate too early and needlessly.

DR JOHN HOMANS, Boston Dr Maurice Richardson and those of his school, in my day, closed all their wounds with through-and-through sutures through all the layers, and even then that was a very old procedure. It was one that my father had used in his early oophorotomies. I dare say it came from England. In any case, I have never heard of any infection of the peritoneal cavity, I think that the sutures cut through the peritoneum very soon and that the latter must heal behind them within three or four days.

I question the statement that through and through sutures through all the coats of the abdominal wall cannot

be used, because apparently such sutures are much more effective if they include the peritoneum. Otherwise, the peritoneum very often opens up from behind because of pressure within or some other reason, and the whole incision opens just as though the through-and-through stitches were not there. I believe that if one is going to use such sutures to hold the abdominal wall, one should include in them the peritoneum.

DR. LAHEY We have closed about 100 patients without putting the stay sutures through the peritoneum, and I do not believe there has been a single evisceration in the entire series. It occurred quite frequently when we employed layer catgut.

A MEMBER Do you mean that you put nothing in the fascia?

DR. LAHEY No I do not want anyone to infer that this method has the slightest originality. Kennedy and many others have used it. One of the reasons why I prefer to close the peritoneal cavity with a layer of catgut, instead of putting the through and through sutures into the peritoneal cavity through the parietal peritoneum, is that with an antecolic anastomosis of the Hofmeister type the two loops of jejunum are directly beneath the abdominal wall, and adhesions must not be allowed to form between the loops and the areas of possible reaction about through-and-through sutures that pass through all the layers.

## DAVID WILLIAMS CHEEVER\*

FRED B LUND, M.D.

BOSTON

THERE is one advantage which we older men have over you of the younger generation which nothing, not even time, can take from us. I mean the intimate knowledge and friendship of those heroes who were our teachers and seniors when we were beginners in the profession. We knew them because we lived with them, and learned to know their skill, kindness, courage, ability and generosity. You can never know and appreciate them in the same way, for the "oblivion of time" has come between. Such men were John Homans, Maurice Howe Richardson and, in the highest degree, David Williams Cheever, the subject of this sketch which will attempt, however inadequately, to describe the impression he made on us who were among his students and pupils toward the end of his career as a teacher. I often wonder whether it is possible for you to feel the same reverence for your seniors that we felt for ours. It hardly seems so.

The faculty of the Harvard Medical School, when our class entered it fifty years ago, was a most distinguished set of men. Thomas Dwight, professor of anatomy, Henry Pickering Bowditch

in physiology, Reginald Heber Fitz in pathology, occupied us for the first two years, and we then came by the route of bedside clinics at this hospital under the influence of the remarkable man to whom this amphitheater is being dedicated. Tall, erect, thin, rather delicate-looking, austere, yet with a sense of humor and a most engaging smile, we noticed that he wasted no words in his description and demonstration of the cases in the wards. Deliberate in motion and speech, his wonderful use of English, his choice of the *mot juste* and absence of rhetorical flourish, served to impress his statements on the minds of his students. His lectures, which covered the whole subject of surgery, were delivered in a manner so clear and concise that they could hardly fail to be retained in the memory. Naturally he was a most popular teacher, and great was the dismay of the students when, only two years after we had listened to these lectures, they were discontinued by his resignation at the age of sixty-two. His lectures were delivered without notes, yet when taken down by a stenographer and published almost without revision they formed a marvelously clear epitome of the surgery of the time. Didactic

\*Read at the dedication of the David W. Cheever Amphitheater, Dowling Building, East City Hospital, November 7, 1933.

survived the operation. Five are still living, 2 had recurrences, 1, an ulcer case, was not traced, 2 are living and well, at fourteen months and four and a half years respectively. Of the many cases reviewed where long survival is mentioned—that is, a period of four years or more—there seemed to be a certain recurrence as to the exact condition of the patient. I found, however, that in a number of these cases there developed a condition similar to pernicious anemia, and in some a true pernicious anemia, 1 such case being recorded at the Mayo Clinic in which the patient survived for three years. Allen attributes this condition to the fact that these patients do not eat meat. Merklen and Froehlich made a study of the blood of 28 gastrectomized patients, and concluded that gastrectomy does not cause pernicious or any other kind of anemia. They cited several reported cases of pernicious and other anemias which occurred in gastrectomized patients, but they considered these incidental and not due to the gastrectomy.

As a basis for a satisfactory result, I suggest the following: that the patient be able to regain, at least partially, the position he previously occupied in his community, that he give pleasure to his relatives and friends rather than be a cure, and that he derive enough enjoyment from life to make existence bearable. Practically none of the many case reports included any such information. In fact, a few left one with the impression that the lives of the patients had been prolonged not so much for their benefit as to demonstrate a feat of surgery.

Warrick reported autopsies on 176 patients who died of carcinoma of the stomach. Of these cases no metastasis was demonstrable in 23 per cent. This clearly indicates that many cases with a possibility of cure are overlooked. At present, with our improved methods of examination and diagnosis, such cases will be given the benefit of operation, with continued improvement along these lines we may hope for much earlier diagnoses, and the associated advance in technic will bring more favorable results. Thus far, at least, radical surgery offers the only known hope for the successful treatment of carcinoma of the stomach.

DR PEIRCE H. LEAVITT, Brockton, Massachusetts. I was very much impressed by the large number of patients with ulcer who have appeared at Dr. Lahey's clinic. There were so many that I suspect that surgeons like myself practicing in much smaller cities than Boston, see very few cases in comparison, in fact not enough to warrant our doing gastrectomies. I believe that such cases should be left to specialists in this brand of surgery. The man who sees them only occasionally should not attempt to treat them, and if I myself had an ulcer of the stomach I should want it treated by someone who had cared for a great number of cases of this type.

I compliment Dr. Lahey on his excellent development of the operation, and the marked decrease in mortality he has been able to show.

DR EDWARD R. LAMPSON, Hartford, Connecticut. When Dr. Lahey published several years ago an article on subtotal gastrectomy for duodenal ulcer, he reported a mortality of 18.5 per cent, as I remember it. He showed a great deal of courage in presenting a mortality of that degree. He then reported 47 cases with a 10 per cent mortality. He has now done nearly 50 consecutive cases with no deaths. This shows that he was absolutely justified in continuing the method that he finally adopted.

While in England a year ago I spent my afternoons visiting the London hospitals, where I found that they were largely employing the method of subtotal gastrectomy in their cases of gastric and duodenal ulcer. At the Mid-

Another important point which I stressed yesterday morning was that, when the jejunum is anastomosed to the end of the stomach, the suture should be started near one mesenteric border. If done in this way, one finds, when the anastomosis is complete, that a sufficient portion of the lumen remains free. Another mistake which has undoubtedly been frequently made is to run the anastomosis of the jejunum to the stomach obliquely across the jejunum instead of exactly parallel with the mesentery, thus causing twists in the jejunum which do not drain well. These are technical mistakes, but they represent features which tend to create postoperative difficulties in this operation.

at the hospital established his reputation. In 1866 he was appointed adjunct professor of anatomy, soon after professor of clinical surgery, and finally, in 1882, he was given the chair of surgery on the resignation of Henry Jacob Bigelow. His appointment met with opposition because the professor of surgery heretofore had always been a member of the staff of the Massachusetts General Hospital, but in the discharge of his duties Dr. Cheever, by his honesty, courtesy and fairness, so endeared himself to his younger colleagues, and so thoroughly demonstrated his fitness for leadership, that interdepartmental relations were most pleasant. His younger colleague and eventual successor, John Collins Warren,<sup>2</sup> wrote

Our relations on the teaching staff were always regarded by me as leaving nothing to be desired. The elder man always took a sympathetic interest in his junior's welfare. No occasion calling for a word of encouragement or congratulation was passed unnoticed, and if criticism was necessary, it was always skillfully concealed under the guise of fatherly suggestions. I have often wondered whether the currents of academic life flowed as smoothly in other departments of the University as they did in ours when he was chief. Perhaps it was because his depth of character brought a serenity with it which permeated the whole staff, one and all of whom were glad to acknowledge him as leader.

There could hardly be a greater contrast between two men than between the brilliant, erratic, impressive Bigelow and the steady, calm serenity of the dependable Cheever. On the comparison of their whole teaching careers, Dr. Cheever is not the loser. He served until 1893, when he was made professor emeritus, and the following year received the degree of LL.D. from his alma mater. He served as overseer of Harvard College for twelve years. He was a member of many medical organizations, including the Massachusetts Medical Society and the American Surgical Association, of which he was president in 1889, the seventh year of its existence. His presidential address,<sup>3</sup> only seven pages long, was the best summary of surgery up to that time and the best prophecy for the future that I have ever read. He did not, as others less wise had done, state that surgery had already reached the limit of progress of which it was capable. The title of his paper was "The Future of Surgery without Limit." It begins as follows: "Fellows of the American Surgical Association, I believe that we are warranted in saying that the future of surgery is without limit. I deduce this conclusion, first, from considering what the mind of man has already done, second, from the future possibilities of fields hitherto unexplored, but now opening up to science. There can be but

two limitations, either in the mind of man, or on the subject." Then he went on to sketch the development of the mind of man from the anthropoid ape to the present, and the progress of invention and discovery through the ages. The truth of his prophecy is proved by the fact, which I believe to be true, that surgery has made more progress in the last hundred years than in the preceding five thousand years since its first description by the great Egyptian, Imhotep. This address should be read and pondered by every member of our profession for its rational combination of conservatism and optimism.

We who knew Dr. Cheever at the end of his career hardly realize the many activities of his earlier years, and his contributions to our art. He was bold and conservative at the same time, absolutely unruffled by emergencies (which occurred less often because his work was so well planned, and rehearsed, if necessary, beforehand on the cadaver). He was a good gross pathologist before the days of histology, with a perfect knowledge of anatomy, and rare surgical judgment. In his younger days he made many contributions to some of the more difficult fields of surgery. Esophagotomy for foreign bodies was associated with his name, and he was particularly neat and skillful in its performance. I remember well my sensations when he removed through the neck a jackstone from the esophagus of a little boy brought down to him by our family doctor in Concord, New Hampshire. The esophagoscope has largely removed the necessity for this operation, but I finally performed one, forty years later, to remove a tooth plate which the laryngologist could not handle. I thought of Dr. Cheever's operation so skillfully performed many years ago. He removed cancers of the tonsil through the neck (no minor operation), and corresponded with the great Billroth on the subject. He performed plastic displacement of the upper jaw for removal of tumors of the nasopharynx, perfected Wood's operation for the radical cure of hernia, performed the first two consecutive successful ovariectomies in Boston, in 1873 (before antiseptics), and was one of the earliest in this region to do cesarean section. He corresponded with Olivier, of Lyons, on the subject of his subperiosteal resection of the long bones, with Reginald Harrison, of London, on the subject of Cock's operation for impermeable stricture, which he was performing, with Holmes, of London, in regard to excisions for coxalgia. His success shows the advantage which comes to a young man who is given early the opportunity for major work, without waiting, as many did, through the long years of the humdrum and

lectures have been the subject of criticism in later times, but certainly in the hands of Dr Cheever they approached perfection as a teaching medium. We saw him in the operating room, careful to the last degree, not slow in execution, bold and resourceful. We noticed how dependent upon his judgment were the younger members of his staff, his tact and kindness with them and his consultants, the feeling of respect and almost reverence with which they regarded him. We compared him with the other members of the surgical and anatomical departments, the jolly genius who was Maurice Howe Richardson, the brilliant Charles Burnham Porter and the incomparable "Honest John" Homans, who were all younger at that time and were perhaps more in the public eye, while he had passed the zenith of his activities, and was not so active as he had been. His characteristics may be summed up in the one word dependable. The straight, slender figure and the calm, steady gaze belonged to a man as sensitive and keen in mind as he was calm in appearance. He was a man even as you and I in his fears and feelings, but an iron will concealed his anxiety and made him serene and steadfast in reality as in appearance, and his frail physique, by careful management and temperate living, became capable of any amount of hard and nerve-racking work.

Who was this Dr Cheever in whose honor we are met today, and what were the circumstances that contributed to his character and success? He was born of good Puritan stock at Portsmouth, New Hampshire, in 1831, the son of Charles Augustus Cheever, who had an excellent reputation as a surgeon, and the grandson of Abijah Cheever, who had served as a surgeon in the Revolution and practiced near Boston. He was descended in the seventh generation from Ezekiel Cheever, who came to Massachusetts in 1637 and was for many years master of the Boston Latin School.

Cheever was educated at home by his father and mother and at the Portsmouth High School, and later had the privilege of reading Latin with the late Andrew Preston Peabody, then his pastor, in Portsmouth. He developed a love for the classics which continued all his life, and was a solace in his later years. I believe that his thorough training in the classics was not unimportant in the development of the concise and accurate English shown in his lectures and writings. He entered Harvard at the age of sixteen, and was graduated in 1852. He<sup>1</sup> wrote of his college career

This was the great privilege of my life. I studied Italian with Longfellow, who extemporized Dante

into English verse, German with Bernard Rolker, whose sonorous pronunciation and poetic temperament converted a dry recitation into an inspiration of Schiller and Goethe, botany with Gray, never to be forgotten for his simplicity and purity, Greek with Felton, genial and human, Latin with Beck, a German critical scholar, modern literature with James Russell Lowell, natural history with Agassiz, metaphysics with James Walker, who had a great influence in my life.

What one of us under the "elective system" has attained a better balanced education than that!

Dr Cheever's father died soon after his graduation, and though himself a physician, advised his son not to study medicine. So after graduation Dr Cheever went abroad to look about him and decide what calling he should follow, and remained eighteen months, most of the time in Paris, in association with medical students and students of art. On his return, with his mind made up, he entered the medical school in 1854, at the age of twenty-three. Of the medical faculty he<sup>1</sup> writes "There were eight professors, of whom four were interesting to me. Above all anatomy as such, and as charmingly taught by Oliver Wendell Holmes. Dr Bigelow's lectures were spectacular and dramatic, a first-class lecturer, clear, logical, with a dry wit and a broad metaphysical mind."

Clinical facilities were limited, but a few fortunate men who knew the trustees of the Massachusetts General Hospital and applied to them for positions secured places as "house pupils." Dr Cheever did not know the trustees and was too proud to apply. He got his training for a year at the State Hospital at Rainsford Island, returned to the school, was graduated in 1858 and entered general practice in Boston.

The surgery of that day (which was previous to asepsis) was so limited in amount that no young man tried to support himself exclusively by surgical practice. Later, after asepsis, ovariectomy and appendicitis had come on the scene, the late Maurice Richardson was the first real specialist in surgery in Boston. Dr Cheever was an excellent medical practitioner, thorough, devoted, never in a hurry, resourceful. In 1860 he was appointed demonstrator of anatomy, and for the next eight years prepared the dissections for Oliver Wendell Holmes's lectures, revolutionized the teaching in the dissecting room, doubtless developed his skill as a teacher, and was strongly turned in the direction of surgery.

In 1864, when the Boston City Hospital was established, he was appointed to the staff of surgeons, at the age of thirty-three, the youngest member of the body. He performed the first operation in the hospital, and from that time on, the best part of his active life was devoted to that hospital and the medical school. His brilliant work

at the hospital established his reputation. In 1866 he was appointed adjunct professor of anatomy, soon after professor of clinical surgery, and finally, in 1882, he was given the chair of surgery on the resignation of Henry Jacob Bigelow. His appointment met with opposition because the professor of surgery heretofore had always been a member of the staff of the Massachusetts General Hospital, but in the discharge of his duties Dr Cheever, by his honesty, courtesy and fairness, so endeared himself to his younger colleagues, and so thoroughly demonstrated his fitness for leadership, that interdepartmental relations were most pleasant. His younger colleague and eventual successor, John Collins Warren,<sup>2</sup> wrote

Our relations on the teaching staff were always regarded by me as leaving nothing to be desired. The elder man always took a sympathetic interest in his junior's welfare. No occasion calling for a word of encouragement or congratulation was passed unnoted, and if criticism was necessary, it was always skillfully concealed under the guise of fatherly suggestions. I have often wondered whether the currents of academic life flowed as smoothly in other departments of the University as they did in ours when he was chief. He performed the first operation in the hospital, and from that time on, the best part of his active life was devoted to that hospital and the medical school. His brilliant work

<sup>1</sup>This was the great privilege of my life. I studied Italian with Longfellow, who extemporized Dante

which attracted attention he resisted the attempts of lawyers to extract from him confidential evidence revealed in the course of his practice

He was for many years president of the Medical Benevolent Society, and aided in every way those whose old age had come and brought with it indigence.

Dr Cheever suffered most of his life from a functional trouble, which he bore so bravely and uncomplainingly that few realized he had it. The iron will that carried him through emergencies without a quaver so controlled his impulses that he never complained, or even spoke of his indigestion. Fortunately at the age of sixty he was cured by abstention from meat.

Dr Cheever loved outdoor life, rowing, fishing, horseback riding and walking. His figure on his white horse was a familiar one on the Fenway. He was frequently accompanied by his son, David. He loved the beauties of nature, and the ceaseless changes of the sea and sky. He was most happily married, was devoted to his family, which was his first interest, and took the greatest delight in his children and grandchildren. When he retired from active practice he spent his leisure in outdoor life, resumed his study of the classics and thoroughly enjoyed his family. He loved travel and the broad knowledge of humanity which it brings. He was loved, even revered, by his patients, his relations with them were in conformity with his character and high standards. As Dr Cheever advanced in age his physical powers failed, but his mental powers persisted in full strength to the end, which came December 27, 1915, soon after his eighty-fourth birthday, after a short illness, when he was surrounded by his family and attended by a physician who was a beloved friend. His son, David Cheever, whose brilliant success in his profession must have cheered the later years of his life, was the only member of the family absent, being in France doing his bit for the wounded in the World War.

At the meeting of the Boston Society for Medical Improvement on April 16, 1916, George Washington Gay,<sup>6</sup> Dr Cheever's lifelong associate and intimate friend, delivered a memorial address which is a model of its kind, it begins as follows:

Any eulogy of Dr Cheever is to be limited only by good taste and discretion. It would be difficult to overestimate his sterling character, his high ideals, his fine motives, his strict integrity and his exceptional service to the profession. His life was replete with wise and efficient activities. For more than half a century he was held in the highest esteem by the members of the medical profession, the court of last resort in determining the character and ability of any physician.

The esteem and appreciation shown in this memorial demonstrate that the longer and closer were

one's associations with Dr Cheever, the more one came to admire and respect him. Dr Gay's memory is fresh in the minds of many of us oldsters. He was a skillful surgeon and most estimable man, came, like Dr Cheever, from New Hampshire, and served as his associate on the staff at the Boston City Hospital during almost the entire time of his own service.

In 1918 a new amphitheater was dedicated at the Boston City Hospital to Dr Cheever, the latest thing in amphitheaters at the time, and expected to last for a long term of years. It was not realized, however, that as time progressed, for reasons of asepsis, less and less operating would be done in large amphitheaters before large audiences, and more and more would be performed in the small, well-equipped operating rooms with the latest equipment for lighting and protection from bacteria. The new amphitheater is and should be designed for lectures, meetings, and so forth, where large audiences can be accommodated. At the time of the dedication of the old amphitheater, Dr David Cheever, the distinguished son of a distinguished father, delivered a most charming and adequate appreciation of his father, and presented the trustees with this [pointing] marvelous relief in bronze, the work of the late Bela Pratt. It is one of the best portraits the artist ever made, as one looks at it one almost believes that the portrait is alive, so well does it catch the fleeting expression of Dr Cheever at some instant in his life. As we look upon it we compare the subject of it with all the other surgeons we have known, and as we go over them all in retrospect we can think of certain qualities of the man in which none surpassed him. Among them are honesty, character, intelligence, interest in his work, diligence, mercy and charity, scholarship, breadth of outlook, optimism, knowledge of his profession.

Gentlemen, we are looking upon a portrait of a man to whom we may give the proud title of a gentleman and a scholar. Dr David Cheever heard his father say on some occasion, "I have tried to elevate the profession," and writes "That really expresses in a nutshell the spirit of his relations to medicine, whether in clinical medicine and surgery, or in teaching, or in the promotion of the nursing profession, or in public relations, and it may be fairly said that he accomplished a great deal in this direction."

May our medical school and hospital continue, as in the past, to honor Dr Cheever's memory—a memory on which his family may look with pride—and to feel a joy greater as the years go on, since time in its passage steals away the sense of recent loss. May the staff who are now bearing

hurry of the outpatient department. Certainly in Dr Cheever's case responsibility could not have fallen into more competent hands.

He was interested in the careers of his former students, and followed them up so far as he could. He established a scholarship for deserving first-year students. He published many monographs on surgical subjects, edited the five volumes of the Boston City Hospital reports from 1869 to 1894 and wrote much of the portion of the reports concerned with surgery, notably two important essays, "Medicine as a Trade" and "Medicine as a Profession." The former presented all the difficulties, the long and expensive study, the abuse of medical charity, and so forth, while the other emphasized the solid satisfactions to be gained from the profession. I quote the last sentence of the second essay: "The resources of our profession are endless in delight, and if you find in the beginning that you love it you will never cease to be happy in its pursuit." Other characteristic titles are "Is the Study of Medicine a Liberal Education?" "Does Surgery Advance?" His answers were that it is, and does.

A paper<sup>5</sup> describing Dr Cheever's three early ovariectomies, with two recoveries, was published in 1873, and it is noteworthy that in 1 case in which the patient recovered the vessels of the pedicle were tied separately and the pedicle was dropped into the abdomen, instead of being brought outside with the clamp left on, as was the custom of that time.

To speak generally, Dr Cheever's papers on professional relations and other general subjects were admirable in their conciseness and philosophical grasp, and as has been mentioned above, his feat of delivering a course of lectures on surgery without written notes, so clear and lucid that a stenographic report of it could be published almost without revision, is an instance of an intellectual *tour de force* unexampled so far as I know.

Many were the pithy sayings credited to him. To medical students entering practice he said "Choose your place and stick. Work all the time, always work—anything connected with the profession." Placing his own steady hand beside the trembling hand of a young patient with delirium tremens, he said, "An old man temperate, a young man intemperate." He told his pupils "The future is full of hope, and let's advance with a confident heart, still holding fast to that which is good. The magnet does not vibrate. The sun and stars are eternal in their courses. Nothing can deflect from his course him who studies, hopes, believes, works." One other true saying of his must be quoted here. "Whatever success I have

won has been due to a peculiar quality of my mind, concentration, one thing, only one thing, always one thing. A doctor, only a doctor, always a doctor. One school, one hospital, one pursuit, one profession. That has been my rule and my course." So he summed up his life's work.

Dr Cheever's long career as a surgeon and teacher embraced the pre-antiseptic period (he assisted his father at certain operations in Portsmouth even before anesthesia was discovered), the slow and hesitating adoption of antiseptic methods and the final achievement of the aseptic methods which we employ today. Great and indomitable must have been the heart of the surgeon before antiseptics, when the slightest operation might be followed by septicemia and death, and when, as Dr Cheever told us, amputation was the rule for nearly all cases of compound fracture, so great was the danger and difficulty of sepsis involving the bone.

Then came the slow and hesitating adoption of antiseptics, the carbolic solution and spray, the inevitable slips made by surgeons who had no training in bacteriology, and who could not recognize the breaks they inadvertently made, and finally the adoption of the aseptic technic, with the only use of antiseptics reserved for the skin, which cannot endure boiling temperatures, and the innumerable refinements connected with draping and technic in general. Hand in hand with this have gone the enormous improvements in anesthesia—local, spinal, intravenous, intratracheal—which allow us to fit the anesthetic to the individual case. Most of this fell within the active life of Dr Cheever, and so great were his enjoyment and appreciation of surgical advances that, as we have seen, he believed that no limit should be set to future surgical progress.

One of my pleasantest memories of Dr Cheever is the serene and placid way in which he presided at the evening clinical meetings of the staff of the Boston City Hospital, which were held in the library. He was most calm and judicious, and seemed to be saying, "Why so hot, little man?" when some of us waxed enthusiastic over our favorite incision for fracture of the patella, or method for radical cure of hernia, he frequently impressed upon us the fact that there is more than one road to Rome, and that one method may be well adapted to one case, another to another.

Something must be said about his interest in the welfare of his professional brethren and in medical legislation. Serene and self-controlled, he made an excellent appearance before legislative committees, and always made his point clear. He was a thorough believer in the confidential relations between doctor and patient, and in certain cases

which attracted attention he resisted the attempts of lawyers to extract from him confidential evidence revealed in the course of his practice.

He was for many years president of the Medical Benevolent Society, and aided in every way those whose old age had come and brought with it indigence.

Dr Cheever suffered most of his life from a functional trouble, which he bore so bravely and uncomplainingly that few realized he had it. The iron will that carried him through emergencies without a quaver so controlled his impulses that he never complained, or even spoke of his indigestion. Fortunately at the age of sixty he was cured by abstention from meat.

Dr Cheever loved outdoor life, rowing, fishing, horseback riding and walking. His figure on his white horse was a familiar one on the Fenway. He was frequently accompanied by his son, David. He loved the beauties of nature, and the ceaseless changes of the sea and sky. He was most happily married, was devoted to his family, which was his first interest, and took the greatest delight in his children and grandchildren. When he retired from active practice he spent his leisure in outdoor life, resumed his study of the classics and thoroughly enjoyed his family. He loved travel and the broad knowledge of humanity which it brings. He was loved, even revered, by his patients, his relations with them were in conformity with his character and high standards. As Dr Cheever advanced in age his physical powers failed, but his mental powers persisted in full strength to the end, which came December 27, 1915, soon after his eighty-fourth birthday, after a short illness, when he was surrounded by his family and attended by a physician who was a beloved friend. His son, David Cheever, whose brilliant success in his profession must have cheered the later years of his life, was the only member of the family absent, being in France doing his bit for the wounded in the World War.

At the meeting of the Boston Society for Medical Improvement on April 16, 1916, George Washington Gay,<sup>6</sup> Dr Cheever's lifelong associate and intimate friend, delivered a memorial address which is a model of its kind, it begins as follows:

Any eulogy of Dr Cheever is to be limited only by good taste and discretion. It would be difficult to overestimate his sterling character, his high ideals, his fine motives, his strict integrity and his exceptional service to the profession. His life was replete with wise and efficient activities. For more than half a century he was held in the highest esteem by the members of the medical profession, the court of last resort in determining the character and ability of any physician.

The esteem and appreciation shown in this memorial demonstrate that the longer and closer were

one's associations with Dr Cheever, the more one came to admire and respect him. Dr Gay's memory is fresh in the minds of many of us oldsters. He was a skillful surgeon and most estimable man, came, like Dr Cheever, from New Hampshire, and served as his associate on the staff at the Boston City Hospital during almost the entire time of his own service.

In 1918 a new amphitheater was dedicated at the Boston City Hospital to Dr Cheever, the latest thing in amphitheatres at the time, and expected to last for a long term of years. It was not realized, however, that as time progressed, for reasons of asepsis, less and less operating would be done in large amphitheatres before large audiences, and more and more would be performed in the small, well-equipped operating rooms with the latest equipment for lighting and protection from bacteria. The new amphitheater is and should be designed for lectures, meetings, and so forth, where large audiences can be accommodated. At the time of the dedication of the old amphitheater, Dr David Cheever, the distinguished son of a distinguished father, delivered a most charming and adequate appreciation of his father, and presented the trustees with this [pointing] marvelous relief in bronze, the work of the late Bela Pratt. It is one of the best portraits the artist ever made, as one looks at it one almost believes that the portrait is alive, so well does it catch the fleeting expression of Dr Cheever at some instant in his life. As we look upon it we compare the subject of it with all the other surgeons we have known, and as we go over them all in retrospect we can think of certain qualities of the man in which none surpassed him. Among them are honesty, character, intelligence, interest in his work, diligence, mercy and charity, scholarship, breadth of outlook, optimism, knowledge of his profession.

Gentlemen, we are looking upon a portrait of a man to whom we may give the proud title of a gentleman and a scholar. Dr David Cheever heard his father say on some occasion, "I have tried to elevate the profession," and writes "That really expresses in a nutshell the spirit of his relations to medicine, whether in clinical medicine and surgery, or in teaching, or in the promotion of the nursing profession, or in public relations, and it may be fairly said that he accomplished a great deal in this direction."

May our medical school and hospital continue, as in the past, to honor Dr Cheever's memory—a memory on which his family may look with pride—and to feel a joy greater as the years go on, since time in its passage steals away the sense of recent loss. May the staff who are now bearing

the heat and burden of the day keep fresh the memory of this great and good man, and gain from it an inspiration to higher ideals, harder work and more faithful service

## SURGICAL DISEASES OF THE EXTRAHEPATIC BILE DUCTS\*

I S RAVDIN, MD†

PHILADELPHIA

**L**ESIONS of the extrahepatic bile passages are the second most frequent cause for abdominal operations by the general surgeon, yet our knowledge of the physiology and pathologic physiology of this system is still far from complete. Much remains to be done, but the information already available has added greatly to our knowledge of biliary function in health and disease.

When the liver bile is carried to the normal gall bladder certain changes in composition occur. The chloride and bicarbonate are removed. The base, bile salt, cholesterol and pigment are greatly concentrated. On the other hand, when the gall bladder becomes damaged the chloride and bicarbonate concentrations of the gall-bladder bile increase and the bile salt and calcium concentrations decrease. Thus, while the normal gall-bladder bile is acid, the bile from the damaged gall bladder tends to become alkaline.

Observations which we have made demonstrate that in extensive damage of the wall of the gall-bladder, fluid pours into its lumen instead of being absorbed from the bile. This phenomenon partly explains the failure of the diseased gall bladder to be visualized after the administration of sodium tetraiodophenolphthalein, since the dye coming from the liver is still further diluted and visualization of the gall bladder depends on concentration of the dye. Moreover, while in the wall of the normal gall bladder little or none of the dye is absorbed, a considerable amount is absorbed from the bile in a damaged gall bladder.

The degree of damage to the wall of the gall bladder is not stationary. During acute inflammation, and even at times during pregnancy, the gall bladder may not be visualized after dye administration, but at a subsequent period some recovery of the function may take place and the gall bladder may then be visualized. It is thus possible to find gallstones in a gall bladder which was

well visualized after the administration of sodium tetraiodophenolphthalein, and whose walls are only slightly thickened at operation.

Through the kindness of Dr Irving W Potter, of Buffalo, we were able to secure specimens of gall-bladder bile from 65 patients who underwent cesarean operations. The high incidence of gall bladder disease in women who are pregnant or have borne children has naturally led to the belief that there occurs in pregnancy a disturbance in metabolism which predisposes to the formation of gallstones.

The almost invariable hypercholesterinemia in pregnancy, and the absence in normal pregnancy of marked disturbances of the other blood constituents, suggest that the metabolism of cholesterol, of which the majority of gallstones are formed, may be deranged as a result of the gravid state. This hypercholesterinemia nearly always disappears before or very soon after delivery, and as a rule, at the time that calculous cholecystitis is diagnosed the blood cholesterol is normal.

No information is available on the concentration of the bile or blood cholesterol while the stone is being formed. Our early studies<sup>1</sup> showed that both hepatic and gall-bladder bile from patients with gallstones have variations in their composition from that obtained from normal patients. It was of interest to know whether the bile specimens obtained from pregnant women were normal or whether they showed any of the characteristics of the bile from patients known to have gall-bladder disease.

The bile-salt concentrations were all below those found in bile removed from a normally functioning gall bladder. The figures for the gall bladder bile cholesterol in pregnant women were distinctly higher than normal, in fact they were at times as much as five times the normal value. Thus, pregnancy bile contains a decreased amount of bile salt which is so necessary to keep cholesterol from precipitating out in the bile, at the same time the bile cholesterol is increased.

Presented at the annual meeting of the New Hampshire Medical Society Manchester May 17 1938

†Harrison Professor of Surgery University of Pennsylvania School of Medicine surgeon Hospital of the University of Pennsylvania Philadelphia

These changes represent the preliminary ones which may precede the formation of stones, and indicate that the frequent occurrence of gallstones in pregnant women is not a chance coincidence but is the result of some change from the normal, either in the bile put out by the liver or the bile after it has been acted upon by the gall bladder.

From the viewpoint of the clinician, cases of gall-bladder disease, exclusive of cancer, can be divided into two groups—with stones and without stones. There is no certain method of determining in all cases before operation whether stones are present. For several years we have had our patients studied roentgenographically and have studied the material obtained by duodenal drainage. Each method is open to certain errors, but each, in the hands of properly trained technicians, is sufficiently accurate to permit a high percentage of dependable results.

We have found that in gall-bladder bile obtained by duodenal drainage we have a more accurate means of determining the presence of gallstones preoperatively. When a "B" fraction of bile can be obtained the method is 90 per cent accurate in the diagnosis of stones, if the procedure is carried out by a qualified technician, while by x-ray we have positively visualized but 58 per cent of stones.

If one is to rate the accuracy of x-ray diagnosis on the end results of operations in these cases, it must be admitted that we often go astray in the diagnosis of chronic cholecystitis in the absence of stones. For in the gall bladder containing no calculus the end results of cholecystectomy are not nearly so good as in the calculous group.

Each of these methods has its advantages and disadvantages. When the case is studied by x-ray one must be sure that the patient has not vomited or had a bowel movement for at least six hours after the administration of the dye. When the films are made the first should cover the entire abdomen so as to include a gall bladder which may be displaced. At that time the dye should be demonstrable in the colon as a flaky material. Failure to verify these points may lead to an error in diagnosis.

When the method of duodenal drainage is used a "B" fraction is essential. If this is not obtained a positive diagnosis is not possible. Failure to obtain such a fraction, however, does not indicate cystic duct obstruction in every case, as is commonly believed.

Furthermore, the value of an excellent clinical history should not be underestimated, for occasionally too great emphasis is placed on the laboratory findings. They are by no means infallible. It is important to establish as carefully as possible before operation whether gall bladder disease

exists, but it is of equal importance to determine the presence of existing collateral disease.

It is well known by surgeons that one of the major causes of death after operation on the biliary tract is myocardial failure. Riesman and Babcock independently suggested that the streptococcus, which is most frequently the infecting organism in biliary tract infection, also causes myocardial degeneration. More recently Schwartz and Herman<sup>2</sup> have suggested that the myocardial change is the result of a fatty infiltration of the myocardium and that this is merely a part of the general increase in the adiposity of many of the patients who have gall-bladder disease.

For some time I have had the opinion that many of the patients who present evidences of serious cardiac disease at the time of operation had some initial cardiac lesion prior to the biliary tract disease. Though the gall-bladder lesion accentuated and aggravated the existing disease, in many cases it may not have been the sole etiologic factor.

In the last 536 biliary tract cases we have operated on there were 56 patients with evident cardiac disease, 18 of whom had evidence of severe myocardial disease by electrocardiographic findings, with signs of decompensation.

All patients suspected of having coincidental cardiovascular disease are studied jointly by the surgeon and the internist. Electrocardiographic and orthodiagraphic studies are made, as well as a careful physical examination of the heart. The operation is done when the surgeon and internist agree that the preparation has been adequate.

These patients do not, if properly protected before, during and after operation, present the serious risk which we are wont to expect, only 2 of the 56 patients with evident cardiac disease succumbed following operation and 1 of these had common duct obstruction. The observations of Fitz-Hugh and Wolferth<sup>3</sup> in this connection are indeed interesting in that following operation there is very often a rapid and marked improvement in the clinical as well as the electrocardiographic picture.

I cannot pass the cardiac aspects of biliary tract disease without saying a word about the patients with myocarditis and angina pectoris whose biliary symptoms may be so slight as to be overlooked. Many of these patients are relieved of their most distressing symptoms by competent biliary tract surgery. Surely injections of and operations on the sympathetic nervous system should be delayed until after the necessary biliary tract surgery has been accomplished. The surprising thing is that at that time further surgery will often not be required.

In nearly every case in our series there has

been improvement in the patient's cardiac symptoms, and while the end results in this respect may not be so good as those obtained after thyroidectomy in the thyrocardiac patient, they are sufficiently good to warrant operation, the gravest myocardial damage need not be a contraindication. The operation has at times consisted only of a cholecystostomy under local anesthesia. In fact, the remarkable and early improvement which occurred in several of our patients whose gall bladders were merely drained leads us to question whether factors other than infection and mere obesity, such as a reflex phenomenon, may not play a part in accentuating an existing cardiac abnormality.

Diabetes mellitus was encountered in 29 of the last 536 patients in whom gallstone disease was present. This association is more than casual, and in certain cases we must agree that there is at least an etiologic relation between the two diseases.

Joslin has stressed the association of obesity and diabetes. Here again we find a close relation to cholecystic disease, for many of the patients with biliary tract disease are overweight. The combination of cholecystitis and hepatitis results in a liver whose ability to store glycogen is below normal.

The high glucose-tolerance curves seen in patients with severe hepatic disease are often not unlike those of diabetic patients. The association of hepatitis, cholecystitis and diabetes so disturbs the glucose metabolism that problems of the most perplexing character confront the clinician. We have repeatedly observed that the diabetic patient with severe hepatic disease is difficult to standardize. He is frequently thrown into hypoglycemic shock by doses of insulin which would have little effect in the presence of a more normally functioning liver.

The higher incidence of diabetes in our group of patients than is found in the normal population suggests that the patient with long-standing cholecystic disease is more prone to diabetes than is the normal individual. Certainly in those patients who only to a slight degree tend to become diabetic, that is the latent cases, the cholecystic disease may tend to accentuate the condition.

We have become accustomed to thinking in terms of liver damage in biliary tract disease when the patient is jaundiced. That the liver glycogen stores may be just as seriously reduced when there exists a widespread hepatitis is not so well understood, but is nevertheless true, for hepatic parenchyma damaged by infection, cirrhosis and fatty infiltration such as is frequently

observed in long-standing cholecystic disease is not conducive to normal storage of glycogen.

We have run the gamut of liver function tests, galactose and glucose tolerance tests, phosphatase determinations, bromsulfalein tests, hippuric acid tests and many others, and have come to the conclusion that hardly any of these are of constant and sufficient value to deserve much reliance. The latter two are of some value, but the compensatory activity of the liver is so great that extensive liver injury exists before even these tests demonstrate hepatic injury. At such a time the tests are too frequently unnecessary.

The van den Bergh determination is of real help in showing the degree of bile pigment retention in the blood stream. It is, however, not a test of liver function. The hippuric acid conjugation method of Quick<sup>4</sup> is at present the best method available for determining hepatic function, but it too frequently fails to indicate early or moderate liver injury. In an organ whose functions are so diversified it is hardly possible that any one test will ever give us an adequate conception of complete function.

It may be inferred from my remarks that I consider gall-bladder disease entirely a surgical problem. This is not true. To operate on every patient with cholecystitis is a mistake. From 10 to 12 per cent of our population past forty years of age have gallstones. Only those patients with symptoms of indigestion or colic or both, and those with cardiac disease or diabetes mellitus, need be considered for operation. Symptomless stones might well be retained and the patient not be exposed to the dangers, even though these be few, of surgical therapy.

While I speak with some positiveness in regard to the stone-containing gall bladder, it is not possible to do so in regard to the non-calculous gall bladder. Nothing has done more harm to the surgery of the biliary tract than the wholesale removal of the blue, thin-walled gall bladder which grossly and microscopically shows little evidence of disease. Even the gall bladder of cholesterosis is but one evidence of a profound disturbance in the lipid metabolism. It is not an inflammatory lesion, and its removal is too frequently followed by a poor end result and a dissatisfied patient.

Even though the symptoms point strongly to cholecystic disease, the gall bladder should not be removed if careful exploration fails to reveal good evidence of disease. The frequency with which colitis may simulate cholecystic disease is ample evidence that not all pain in the right upper quadrant is the result of biliary tract disease.

Nothing has retarded early operation in patients requiring biliary tract surgery so much as

the fact that from 40 to 60 per cent of the non-calculous cases subjected to cholecystectomy fail to obtain the relief which they expected. Surely if disease of the gall bladder were the cause of the symptoms, the end results in this group should be of the best, for the patients would be in an earlier stage of biliary tract disease.

Surgery of the gall bladder is not the cure for all types of the strawberry gall bladder, for colitis and for dyskinesia of the biliary passages, a lesion which is receiving too little attention in this country. The non-calculous gall bladder and the chronic appendix belong to much the same category, and the surgical treatment of either of these conditions has added to the reputation of the surgeon.

There is a large group of patients who have had one or two attacks of cholecystitis, and in whom the evidence is strongly against the presence of stones, who also should be treated by non-surgical methods to ascertain whether they can be kept comfortable. Should a medical regime fail to give relief from symptoms, surgery can then be done.

In acute gall-bladder inflammation, associated with cystic duct obstruction, early operation is, I believe, desirable, for it permits of cholecystectomy, while the edema, suppuration, gangrene and perforation which so frequently follow acute cystic duct obstruction increase the hazards of either cholecystectomy or cholecystotomy. I find myself in sympathy with those who believe that, in general, delay increases the risk. On the other hand, when the patient is seen three or four days following the onset of the attack, palliation is often desirable, if the evidence points to a subsidence of the acute process.

I do not believe, however, that cholecystectomy should be done in every case regardless of the stage of the disease, for it is often wiser to do a cholecystostomy and drain a localized subhepatic abscess than to open widely an area of limited peritoneal infection. It is rare for the gall bladder to perforate into the free peritoneal cavity, and from this point of view the acutely inflamed gall bladder need not be compared to the acutely inflamed appendix.

It is of the greatest importance that the anatomic relations at the junction of the cystic and common ducts be carefully visualized. The damage to an abnormally placed right hepatic duct may prove difficult to repair even though the injury is observed during the operation. Ligation of an anomalously located hepatic artery will result in death, and the catastrophe has infrequently been ascribed to cardiac failure.

There seems still to be a difference of opinion

as to whether the common duct should be opened in the absence of jaundice. We find that in the presence of common duct dilatation, even in the absence of a previous history of jaundice, this is often a wise procedure. Increasing experience with common duct exploration in non-jaundiced patients has convinced us that Lahey is correct. The dilated common duct, especially when there is an accompanying dilatation of the cystic duct, frequently contains stones. The time to remove these is at the original operation.

The question of whether to drain after cholecystectomy is still a moot point. It is our practice to drain with a small soft-rubber tube. One of the most distinguished advocates of non-drainage in this country has said that failure to drain will be regretted in not more than 2 patients in 100. If this be true the mortality of simple cholecystectomy for calculous or non-calculous disease is doubled by failure to introduce a safety valve in the event of bile leakage and threatened bile peritonitis.

While the problems associated with simple gallstone disease are numerous, they are now more clearly understood and there is a more or less generally uniform understanding concerning them. When, however, a stone passes into the common duct, and jaundice occurs, the problems confronting the patient and the clinician are greatly multiplied, their complexity is increased and our understanding of the pathologic physiology which follows biliary obstruction is not clear.

The problems involved in the successful treatment of patients with obstruction of the common bile duct are often so numerous and so difficult of solution that one is surprised that the mortality is not higher than it now is. Whether the obstruction is due to a stone, a tumor or cicatricial stenosis, there occurs with the advent of ductal occlusion an increase in the pressure in the intra-hepatic and extrahepatic bile ducts. As a result of this, the liver cells attempt to carry on their manifold functions against an increasing pressure obstacle. When, after complete ductal obstruction, the pressure in the hepatic ducts reaches 330 mm of the bile itself, hepatic secretory function ceases, so far as any normal function is concerned.

Even at this time many of the functions of the liver continue with little evidence of interference. Glycogenolysis and glycogen deposition are affected but not completely suppressed. Urea continues to be formed. Fibrinogen formation is not affected. Thus the tangible functions are continued in the face of complete secretory suppression.

There occurs at this time a failure of bile pigment to pass into the common duct and, as a

corollary, a retention of bile pigment in the blood with resultant evidences of jaundice. The degree of bile pigment retention depends on several factors. If the obstruction is associated with a normally functioning gall bladder, as occurs in carcinoma of the head of the pancreas or of the papilla of Vater, deep icterus may be delayed for a time.

When the hepatic secretory suppression occurs, the mucous secretion of the bile ducts dilutes the trapped bile, and as the pigment is absorbed by these cells, hydrohepatosis results, at which time so-called "white bile" fills the hepatic ductal system. It is during the state of partial liver insufficiency that so many of these patients seek surgical aid.

In 1929 I<sup>5</sup> reported evidence showing that the glycogen stores of the liver may be severely affected in complete common duct obstruction. Since the function the liver plays in carbohydrate metabolism is among its most important ones, any interference with this metabolism is of considerable significance. We have, however, concluded that too much emphasis has been placed on the carbohydrate aspects of liver function in biliary tract disease, and too little on the metabolism of fat in the liver.

It is true that normally a high liver glycogen is associated with a low liver fat, but it is possible to have a high glycogen content of the liver and simultaneous high liver fat. Moreover, it has not been demonstrated that with the methods now used during the period of preoperative treatment the liver fat can be considerably affected.

Of the greatest importance is the fact that in the presence of liver damage in association with hepatitis and common duct obstruction, large amounts of fat may remain in the liver after what we have believed to be a vigorous type of glucose therapy. This we have demonstrated in patients we have prepared for operation.

It is, we believe, the amount of fat in the liver, regardless of the glycogen level, that conditions the precipitation of liver injury after the use of volatile anesthetics. Thus, a high liver glycogen will not protect against liver injury following the use of chloroform ether or Vinethene if the amount of fat in the liver exceeds 14 per cent, which is only one and five-tenths to two times the normal amount. Furthermore, such a liver is more easily damaged by the anoxemia associated with nitrous oxide and oxygen anesthesia or even spinal anesthesia when accompanied by marked hypotension.

We have repeatedly observed that the depletion of liver glycogen permits additional fat to come to the liver. If, as a result of cell injury,

either from obstruction, infection or any other factor causing a depletion of the glycogen reserve, the liver fat stores are increased, liver necrosis may occur during anesthesia. Liver anoxia is known to exist in common duct obstruction. Thus, a number of factors are associated to produce a vicious circle leading to further liver injury. And the additional injury precipitated by operation and anesthesia may be the important factor in the end result.

It is because of the manifold problems which confront us in these patients that I wish to discuss a rational therapy for preparing the bad risk biliary group with or without obstructive jaundice for operation, as well as certain factors in the operative and postoperative therapy.

Waltman Walters has called attention to the importance of operating on severely jaundiced patients at a time when the level of bile pigment retention in the blood is more or less stationary. The significance of this observation is only too frequently overlooked.

There is no doubt in my mind that the patient who is operated on when the van den Bergh shows a constant level of the serum bilirubin, whether this be high or low, is better able to withstand the additional trauma of operation than is the patient who is operated on in the face of a rapidly rising bile pigment concentration in the blood. This is one of the reasons why I do not believe it is necessary to rush the jaundiced patient to operation. A few days or even a few weeks of careful preparation in certain cases is of more importance than the fact that delay in operation prolongs the period of jaundice. If the serum bilirubin is rising we wait until it has reached a stationary level. If it is falling, we wait until the maximum improvement has taken place.

Since carbohydrates are the major source of liver glycogen, an attempt should be made to increase the carbohydrate intake prior to operation. This may be accomplished in part by frequent high carbohydrate feedings by mouth, reinforced by the intravenous administration of glucose. The anorexia from which so many of these patients suffer can be corrected by the use of large amounts (750 international units) of vitamin B<sub>1</sub> daily plus the use of lyophilized human or pig's bile. However, it must be remembered that even though the glycogen stores are temporarily replenished, they are again rapidly depleted by the very factors which initiated the process in the beginning—ductal obstruction. It is therefore incorrect to assume too much from the simple preoperative administration of glucose unless the therapy is pushed by every available means and over a sufficiently long period of time.

The glucose which is given preoperatively should be given very slowly, since the sugar tolerance is greatly reduced. As it is usually administered by an intern, from 50 to 100 gm may be introduced in ten or twenty minutes and fully a half or more of the glucose may merely flow out in the urine. It has been our experience that spilling over into the urine will not occur if not more than 20 gm per hour is injected intravenously into the average-sized adult.

Since our attention has been focused more directly on the fat content of the liver in the preoperative period, we have changed our preoperative therapy. Our investigations have shown us that it is only possible to increase the glycogen stores greatly during this period by the most intensive carbohydrate feeding. Nevertheless it is essential to rid the liver of the accumulated fat which may be present. The addition of protein to the high-carbohydrate diet in the amount of 14 per cent of the total calories is, we believe, useful in accomplishing this. The protein-carbohydrate diet is the best diet where a low-fat liver is desired.

One of the most distressing complications of operation on the jaundiced patient is hemorrhage. There has existed no satisfactory explanation why, given two patients with an equal degree of jaundice from common duct obstruction, one will bleed after operation while the other goes on to an uncomplicated recovery, until Quick<sup>8</sup> began his studies on the prothrombin time of these patients.

We have at our disposal at the present time, in the study of prothrombin time, a satisfactory method of prognosticating which patient will bleed and which will not. The venous pressure bleeding time, recently suggested by Ivy<sup>7</sup> for this purpose, and the sedimentation rate of Linton have not proved satisfactory in our hands.

The prothrombin time is studied by us in every jaundiced patient. Bile feedings are immediately begun, either in the form of lyophilized bile or by the administration of sodium deoxycholate. In addition we are using a potent source of vitamin K as suggested by Greaves and Schmidt.<sup>9</sup> Since this method of preparation was begun we have not had a single serious case of postoperative hemorrhage.

It is of course possible that the liver injury may be so severe that diet and bile and vitamin K may occasionally prove ineffectual, but the rapidity with which improvement of the liver may take place under suitable conditions leads me to believe that such cases will be rare.

Regardless of the method of preparation, up to the time we began the use of bile and vitamin K in the preoperative period, hemorrhage incidence

in our patients remained approximately the same. With this method of therapy, surgeons need no longer lull themselves into a sense of false security by pouring calcium into the veins of their patients. The occasional use of small transfusions in the preoperative period is undoubtedly of advantage, and in the period prior to the use of bile and vitamin K it did more than anything else to reduce the deaths from hemorrhage.

One can hardly discuss treatment without referring briefly to certain aspects of the operation, for while more adequate preoperative and postoperative care has contributed to a reduction in the morbidity of operations on the biliary tract, certain factors concerned with the operation itself have, in our hands at least, contributed in large measure to the safety of the bad-risk patient.

We believe that the most satisfactory anesthetic in the biliary tract cases is spinal anesthesia. If the patients are given ephedrine prior to the administration of the anesthetic, as suggested by Ferguson and North,<sup>9</sup> and if the anesthetic does not exceed 150 mg of novocain, the drop in the blood pressure is never alarming and the facility with which the operation can be done adds greatly to the safety of surgical intervention. So far as I know, spinal anesthesia alone, with the exception of local anesthesia, will permit of extensive operations on the biliary tract without in any way affecting the liver tissue.

Contrary to general opinion, nitrous oxide and oxygen anesthesia is not safe in the jaundiced patient. The increased anoxia which this anesthetic induces in the liver cells may prove of serious consequence in that further liver degeneration and necrosis may occur. Even Cyclopropane, which permits the use of a high concentration of oxygen, has not proved a very safe anesthetic in such cases.

There are a number of serious problems that may arise in postoperative periods which may be prevented by careful attention to the postoperative therapy. Patients with long-standing or complete obstruction of the common duct should have a slow decompression of the biliary passages after operation. This can be accomplished in a manner similar to decompression of the urinary bladder, except that the obstacle must be provided after operation, since the very nature of the operation tends to result in sudden biliary decompression. If the method of slow decompression is instituted, the sudden hepatic hyperemia which follows the restoration of a free, portal venous blood flow can be controlled.

The use of a slow, continuous intravenous drip of glucose and saline is of the greatest value in the postoperative period. It is after the release

of the obstruction that the liver cells can resume their normal function, and no single substance is so helpful in the postoperative period in aiding the hepatic cells to recover as is glucose

In the badly jaundiced patients, or in those whose jaundice has been of long standing, we believe that the judicious use of small transfusions—250 to 500 cc—in the postoperative period reduces the mortality and results in a smoother convalescence. The feeding of vitamin K is continued in the postoperative period. It will not be long before there is available a purer preparation which can be given parenterally to individuals with a non-retentive stomach.

In the postoperative care of the jaundiced patient we have found that the early restoration to the gastrointestinal tract of the bile obtained by external drainage is of the greatest value. With the use of our decompression method, bile feeding by a Jutte tube is not required, provided the obstruction has been removed.

The extrahepatic functions of the bile play a most important part in the body economy, and a normal intestinal function will follow the adoption of this method in patients whose total or major bile excretion is flowing to the exterior. Since we began this method we have not observed a single instance of pancreatic insufficiency.

I cannot leave certain of the postoperative problems of the biliary tract patient without saying a word about liver shock. Many theories have been elaborated to explain the condition of profound vasomotor depression which occurs in occasional cases after biliary tract surgery and which, in spite of treatment, frequently results in death. The major types of shock are due to ligation or thrombosis of the main hepatic artery. If this catastrophe occurs there take place hypoglycemia, a falling blood pressure, a rising pulse rate and hyperpyrexia. While glucose may give temporary relief, it cannot save the patient.

Although the character and thoroughness of the operation play an important part in the end result of any biliary tract operation, there remains the small group of patients in whom operation was rightly indicated, but who continue to complain of dyspeptic symptoms. If we exclude those patients in whom, as a result of some postoperative sequelae, certain symptoms continue, there still remains a group in which after a technically perfect operation, which was fully indicated, the expected relief failed to follow. Deaver and others have thought that in many of these patients a chronic pancreatitis accounted for many of the residual symptoms.

The failure to relieve fully certain of these patients can, however, be explained by the change

in function of the gall bladder and the liver in long-standing biliary tract disease. The bile salts, which play such an important role in the activation of the lipases, in the digestion and transport of fat, and, in the absorption of a variety of important vitamins, are reduced in concentration in hepatitis, so that the bile entering the intestine is inadequate to fulfill the role which it normally plays in the digestive and metabolic processes.

Any condition which interferes with the normal enterohepatic circulation of certain of the bile constituents or prevents their formation in normal amounts may result in an interference with the extrahepatic functions of the bile, and dyspeptic symptoms will then persist. Thus, if after long-standing cholecystic disease there results a permanently damaged liver, it is highly possible that even cholecystectomy and common duct operations will not bring the full measure of expected relief from symptoms.

These patients will, however, prove to be the exceptions, for with a clearer understanding of the responsibilities of internist and surgeon the patient will come to operation at a time when surgery can offer its best. With careful preparation for operation, after a critical survey of the patient's condition, with a well-planned operation, which is skillfully executed with attention to the minutiae of postoperative care, complicating cardiac disease, hepatitis, diabetes or even jaundice are no longer the bugbears which they once were, and the surgeon can approach these problems with confidence that the final outcome will be good in nearly every case.

#### DISCUSSION

DR. WALTER H. LACEY, Keene, New Hampshire. Dr. Ravdin's paper is full of common sense and is very comprehensive.

I should like to ask about the type of incision. I have been distressed by the number of hernias that I have had

as a postoperative result, and lately I have broken away from using the mid rectus incision and have used a right-rectus, retracting incision, drawing back the rectus muscle from the midline over to the side. I have also used a stab drain for my drainage wick, outside the line of suture, hoping that I should get away, also, from some of the distressing postoperative symptoms that come from adhesions.

I was glad to hear Dr Ravdin speak about spinal anesthesia, it certainly gives the best relaxation. I have been using the type of spinal anesthesia they employ at the Faulkner Hospital in Boston,—a combination of novocain and pontocaine,—with very satisfactory results. One gets more relaxation and can therefore do a better piece of work.

DR. CHESTER L. SMART, Lacomia, New Hampshire. This is one of the finest papers on gall-bladder disease I have ever heard. It seems ridiculous for a man from up in the country to try to discuss such a comprehensive review. However, there are two or three things that I shall mention.

In 1919, Drs Charles and William Mayo wrote in *Keen's Surgery*. Operations for simple gallstones are exceedingly safe and the mortality does not exceed 0.3 per cent from all causes, and the percentage of cures is very high, at least 95. Mortality from cholecystectomy is 0.3 per cent higher. Since then, the pendulum has swung way over to the other side, and now if one does not remove a diseased gall bladder he is open to grave criticism, indeed, I have occasionally heard doctors who have for some good reason failed to remove a gall bladder accused of something like malpractice by their patients.

I believe that gall bladders are frequently found which are in too bad a condition to remove, and, in such cases, the risk of cholecystectomy is much greater than that of a cholecystostomy. I refer particularly to acute empyema of the gall bladder in elderly or debilitated patients. Frequently these patients are terribly sick. The gall bladder is wrapped about with omentum, occasionally the tip only is visible, and that distended and dark, the ducts are greatly congested and edematous. In these cases a cholecystostomy can be done, the obstructing stone removed, a tube inserted and the wound closed in a minimum of time and with little shock, and frequently under local anesthesia. I am sure that if one were to remove the gall bladder the mortality would be much higher.

I also believe that in cases of acute or chronic pancreatitis the treatment of choice is cholecystostomy with prolonged drainage, a procedure which gives the inflammation in the pancreas the best chance to subside, I mean by prolonged drainage a period of at least three months.

DR. DAVID W. PARKER, Manchester, New Hampshire. I repeat what Dr Smart just said about Dr Ravdin's paper: it is the most intensive, practical report that I have heard for years. I should like to have Dr Ravdin speak a little more fully on the acute gall bladder as we occa-

sionally see it. The pendulum is, perhaps, swinging more toward treating it like acute appendicitis. In 2 of my acute cases, I delayed the operation for several days until the symptoms quieted down, on operating I found a small abscess down around the cystic duct. Of course, if one operates early one has other things to contend with—one is between the devil and the deep sea.

DR. RAVDIN (closing). In the subcostal incision, which we have used for sixteen years, the drainage tube is brought out through the lateral edge of the incision. The incidence of hernia has been about 4 per cent. The late Dr Dan Jones of Boston used this type of incision for many years. I believe that the patient is more comfortable when it is used. Respiratory exercises can be more easily carried out, and the incidence of postoperative pulmonary complications is therefore lower. The exposure of the undersurfaces of the liver and the common duct is, I believe, better than that obtained with any other incision.

As to cholecystostomy, of course there is a place for it. The surgeon who says he never does a cholecystostomy is either losing patients whom he should not lose or is not doing much biliary tract surgery. At another state society meeting which I attended not very long ago, a surgeon reported the results of cholecystectomy for acute cholecystic disease. His mortality was 17.6 per cent. It is true that the mortality for cholecystectomy for acute cystic duct obstruction in the hands of certain surgeons is much lower than that, but one must not consider what it is in the hands of a few surgeons, one must consider what it is in the hands of the majority of surgeons.

On my own service, there has not been a death from cholecystectomy in eleven years. This of course excludes the common-duct cases. But I am sure that had we done cholecystectomy in every case with acute gall-bladder infection I could not make this statement. Furthermore, as I said in my paper, I believe that in certain patients with serious cardiac disease and decompensation, drainage of the gall bladder is sometimes the primary operation and frequently the only one to do. If patients are seen early, cholecystostomy is the operation of choice. But when the patient is seen three, four or five days after the onset of the attack, and as the result of obstruction in the neck of the gall bladder there have occurred gangrene, necrosis and perforation, with subhepatic abscess, which is always a localized abscess, that is a different story. I have seen but 1 case of generalized peritonitis from a perforated gall bladder. The very anatomic relations seem to localize it.

I believe that the wide exposure needed in these cases in order to visualize clearly the cystic and the common ducts increases the hazards of cholecystectomy. In most of such cases we have believed it wiser to do a simple cholecystostomy and drain the hepatic abscess, advising patients to come back in three months for cholecystectomy. If they return in the interim, when the infection has subsided, the separation of adhesions from the gall bladder is an easy process, and cholecystectomy can be done with a minimum of risk.

of the obstruction that the liver cells can resume their normal function, and no single substance is so helpful in the postoperative period in aiding the hepatic cells to recover as is glucose

In the badly jaundiced patients, or in those whose jaundice has been of long standing, we believe that the judicious use of small transfusions—250 to 500 cc—in the postoperative period reduces the mortality and results in a smoother convalescence. The feeding of vitamin K is continued in the postoperative period. It will not be long before there is available a purer preparation which can be given parenterally to individuals with a non-retentive stomach.

In the postoperative care of the jaundiced patient we have found that the early restoration to the gastrointestinal tract of the bile obtained by external drainage is of the greatest value. With the use of our decompression method, bile feeding by a Jutte tube is not required, provided the obstruction has been removed.

The extrahepatic functions of the bile play a most important part in the body economy, and a normal intestinal function will follow the adoption of this method in patients whose total or major bile excretion is flowing to the exterior. Since we began this method we have not observed a single instance of pancreatic insufficiency.

I cannot leave certain of the postoperative problems of the biliary tract patient without saying a word about liver shock. Many theories have been elaborated to explain the condition of profound vasomotor depression which occurs in occasional cases after biliary tract surgery and which, in spite of treatment, frequently results in death. The major types of shock are due to ligation or thrombosis of the main hepatic artery. If this catastrophe occurs there take place hypoglycemia, a falling blood pressure, a rising pulse rate and hyperpyrexia. While glucose may give temporary relief, it cannot save the patient.

Although the character and thoroughness of the operation play an important part in the end result of any biliary tract operation, there remains the small group of patients in whom operation was rightly indicated, but who continue to complain of dyspeptic symptoms. If we exclude those patients in whom, as a result of some postoperative sequelae, certain symptoms continue, there still remains a group in which after a technically perfect operation, which was fully indicated, the expected relief failed to follow. Deaver and others have thought that in many of these patients a chronic pancreatitis accounted for many of the residual symptoms.

The failure to relieve fully certain of these patients can, however, be explained by the change

in function of the gall bladder and the liver in long-standing biliary tract disease. The bile salts, which play such an important role in the activation of the lipases, in the digestion and transport of fat, and, in the absorption of a variety of important vitamins, are reduced in concentration in hepatitis, so that the bile entering the intestine is inadequate to fulfill the role which it normally plays in the digestive and metabolic processes.

Any condition which interferes with the normal enterohepatic circulation of certain of the bile constituents or prevents their formation in normal amounts may result in an interference with the extrahepatic functions of the bile, and dyspeptic symptoms will then persist. Thus, if after long-standing cholecystic disease there results a permanently damaged liver, it is highly possible that even cholecystectomy and common duct operations will not bring the full measure of expected relief from symptoms.

These patients will, however, prove to be the exceptions, for with a clearer understanding of the responsibilities of internist and surgeon the patient will come to operation at a time when surgery can offer its best. With careful preparation for operation, after a critical survey of the patient's condition, with a well planned operation, which is skillfully executed with attention to the minutiae of postoperative care, complicating cardiac disease, hepatitis, diabetes or even jaundice are no longer the bugbears which they once were, and the surgeon can approach these problems with confidence that the final outcome will be good in nearly every case.

#### DISCUSSION

DR. WALTER H. LACEY, Keene, New Hampshire. Dr. Ravdin's paper is full of common sense and is very comprehensive.

I should like to ask about the type of incision. I have been distressed by the number of hernias that I have had

# CHEMICAL AND PHYSICAL PROPERTIES OF VINYL ETHER

Vinyl ether is a clear, colorless fluid which possesses a characteristic odor. This odor is not unpleasant, and we have never had a patient complain about it, or object to the administration of vinyl ether when it was to be used a second time. Owing to its low boiling point ( $28-31^{\circ}\text{C}$ ), vinyl ether is very volatile and vaporizes with extreme rapidity. It decomposes somewhat on exposure to light and air, and hence should not be employed if the containing bottle has been open for more than twenty-four hours. However, when left unopened in the tightly capped, dark-colored bottle\* in which it is supplied, it may be safely stored for a year or more. Vinyl ether is inflammable, its explosive properties being about the same as those of ethyl ether.

## DESCRIPTION OF VINYL ETHER ANESTHESIA

Vinyl ether may be administered in a closed gas machine of suitable type or may be dropped on an open (Yankauer) mask. We have had no experience with the closed-machine method, because it is too expensive, it is also wasteful, since any unused portion of the drug must be discarded. However, in an accident ward where such a machine is being used frequently, this method of administration would probably be quite satisfactory.

In all cases of the present series the open-mask method was employed. Caution must be taken regarding the type of mask, for it is absolutely necessary that a large amount of air be available to the patient at all times. Because of this, a closed mask is unsatisfactory. Nor is it advisable to surround an open mask of the Yankauer type with a cuff or towel to prevent cross-drafts and loss of the highly volatile vinyl ether. This was attempted in 1 case, with resultant cyanosis, which was completely relieved as soon as the towel was removed and the patient was permitted to have more air.

The Yankauer mask, covered with six or eight layers of gauze, is placed over the mouth and nose, resting lightly on the skin of the face so that all inspired air is drawn through the mask and none around it. The anesthetic is then dropped at an even rate, beginning with one or two drops per second, different parts of the mask surface being moistened. At first one is likely to be a little timid in administering this potent drug, but experience with only a few cases gives convincing evidence of its safety and the ease of induction by its use. The excitement stage is

extremely short, and indeed is often absent. In no case in this series did induction require more than forty-five seconds, and in the majority of cases sufficient relaxation was obtained in thirty seconds. With the onset of surgical anesthesia most patients showed a marked rise in the respiratory rate to 40 or 50, a level which was usually maintained throughout the anesthesia. This stimulation of the respirations accompanied general muscular relaxation, and its onset could usually be taken as an indication that sufficient drug had been given to permit starting the operative procedure. However, some patients in the series failed to show this marked stimulating effect, even though unconsciousness and muscular relaxation had been obtained.

The maintenance of the anesthesia at a given level necessitates the continued dropping of vinyl ether, usually at the rate of about one drop per second for the older children and half this rate for infants. After a little experience no difficulty was encountered in continuing the anesthesia throughout the operation. In a few cases salivation was quite marked, and at times it was necessary to remove the mask temporarily and wipe secretions away from the mouth in order to obtain a quiet anesthesia. However, in no patient was the accumulation of secretions sufficient to block seriously the respiratory passages. Eye signs were entirely unreliable, and could not be employed as a guide to determine the depth of the anesthesia. There was often a rolling motion of the eyeballs even though the extremities and abdomen were sufficiently relaxed.

Table 1 Data from Cases with Vinyl Ether Anesthesia

Number of patients with vinyl ether anesthesia	160
Number of patients under one year of age	20
Youngest patient	1 mo
Oldest patient	11 yr
Types of operation	
Incision and drainage of abscess	24
Aural paracentesis	19
Endothermy coagulation of hemangioma	19
Urethral dilatation retraction of foreskin external	
metotomy and so forth	10
Induction anesthetic only — for major operations	5
Esophageal dilatation	4
Suture of laceration	3
Reduction of fracture	3
Miscellaneous	3
Average time for production of surgical anesthesia	30-45 sec.
Average recovery time from removal of mask to return of consciousness	2-3 min.
Average amount of vinyl ether used per case	13 cc.
Number of patients with morphine premedication	17
Number of patients with atropine premedication	33
Number of patients with postanesthetic vomiting	5

\*Not including 3 children with recovery times of 10, 18 and 0 min.

After removal of the mask recovery was prompt, the average patient responding by talking rationally and wanting to sit up in two or three minutes. In only 3 cases was there a recovery period longer

\*Densed in 10-, 25- and 50-cc. bottles.

## THE USE OF VINYL ETHER (VINETHENE) IN INFANCY AND CHILDHOOD\*

### Report of 100 Cases

ROBERT E. GROSS, MD†

BOSTON

**T**HE introduction of vinyl ether (Vinethene) in recent years has made available a new anesthetic which can be particularly adapted for surgical procedures of short duration in infancy and childhood. There has been a long-standing need for a suitable general anesthetic, preferably of an inhalant type, which will produce narcosis rapidly, give adequate relaxation, have a short recovery period, produce little postanesthetic reaction and carry a high degree of safety. All these features appear to be present when vinyl ether is used in adults, and we were therefore prompted to test this drug on younger patients than have heretofore been studied. The following report summarizes our experiences with this anesthetic in 100 babies and children at the Children's Hospital. The results were so satisfactory that the drug promises to assume a permanent place in the armamentarium of one who has occasion to undertake minor operative procedures in young individuals.

In our outpatient department work the use of ethyl ether often causes considerable difficulty because of prolonged recovery periods. In a busy clinic the suture of lacerations, drainage of abscesses, and so forth, under ethyl ether may tie up one or more nurses, who must stay with these patients for an hour or two during the stage of postanesthetic unconsciousness. A similar problem is encountered during the evening or night, when it is necessary to keep some of the personnel on duty while a child slumbers, salivates, vomits, perspires and slowly regains consciousness after having been given a general anesthetic. The use of vinyl ether has greatly changed this situation, and now a child is rarely held more than ten or fifteen minutes after completion of the surgical procedure, for the recovery period is extremely short and the postanesthetic complications are rare.

#### TYPES OF CASES SUITABLE FOR VINYL ETHER ANESTHESIA

Vinyl ether can be used to marked advantage for minor operations which can be completed in five or ten minutes. This limitation on the operative

time is not made because it is unsafe to administer the drug over a longer period, but rather because it is somewhat difficult to maintain an even depth of anesthesia, owing to the extreme rapidity of the action of vinyl ether. Operations have been performed using vinyl ether for half an hour or more, but in such cases careful observation is necessary to maintain the anesthesia on a given plane.

The type of case, then, in which vinyl ether is particularly useful is the one so often encountered in outpatient-department work or in the pediatrician's practice. Within this category may be listed incision and drainage of an abscess or suppurative cervical adenitis, aural paracentesis, dilatation or retraction of a tight foreskin, removal of deeply embedded splinters, dilatation of urethral strictures, external meatotomy, and suture of small lacerations. In a number of cases we have found this anesthesia very useful for endothermy, coagulation of hemangiomas. Sufficient muscular relaxation can be obtained to permit rapid and easy reduction of fractures of the digits or of a Colles's fracture, but more complicated ones had best be treated under some other form of anesthesia. Several times we have attempted dilatation of esophageal strictures under vinyl ether, but this was unsatisfactory, owing to the fact that when the face mask was removed to start dilatation the patient recovered too quickly. In 5 cases vinyl ether was satisfactorily employed as an induction agent (in appendectomy, tonsillectomy, and so forth) because the rapid onset of narcosis was desirable in an excited child. After muscular relaxation was obtained—usually in less than one minute—the vinyl ether was discontinued and was replaced by ethyl ether.

The drug appears to be very suitable for use in even the youngest age groups. Indeed it has distinct advantages in infants because its stimulating effects on the respiratory apparatus ensure an adequate exchange of air and at once dispense with the difficulties in breathing which may be troublesome with ethyl ether and particularly with nitrous oxide anesthesia. We have employed vinyl ether for infants as young as one month, and have been highly pleased with its ease of administration and its apparent safety.

\*From the Surgical Service of the Children's Hospital, Boston.

†Instructor in surgery, Harvard Medical School; surgical resident, Children's Hospital and the Peter Bent Brigham Hospital, Boston.

The experience of all observers who have treated any appreciable number of cases of Type 5 pneumonia has been uniformly favorable. In most clinics, including the Boston City Hospital, the results as judged by the reduction in mortality and the occurrence of rapid clinical improvement have been comparable with or even better than those obtained in Type 1 cases. Experiences with Type 7 and Type 8 cases, on the other hand, have varied widely, most of them have been favorable, and the mortality in specifically treated cases has been lower than that of non-serum-treated cases. One may also include Type 14 pneumonia in infants and young children among those which have given favorable results in clinics where serum has been used extensively.

There are many fundamental reasons underlying the differences in result, and these are in no way different from the circumstances previously encountered in Type 1 and Type 2 cases. Most vital, perhaps, is the lack of adequate experience, that is, the number of cases of the "higher" types in any one observer's experience is too small to make it possible to sift out the necessary important factors, particularly if the data in individual cases are incomplete. Moreover, experience with the production and standardization of these serums, and as a consequence the opportunities for obtaining accurate criteria concerning dosage, are extremely meager.

In dealing with pneumococci of the "higher" types, the difficulties of forming sound opinions multiply enormously. There is great variability among these types with respect to their pathogenicity for man. Very diverse clinical pictures result when they produce pulmonary infections. It is frequently difficult to distinguish in any given patient the type of pneumococcus which is the causative agent in the disease from those which may be habitual or transient residents in the respiratory tract without causative relation to the infection. With a number of these types even material obtained from lung taps, as employed in some clinics, is seldom helpful, since negative results are the rule. Such material is a help in picking out some of the commoner types occasionally missed in the typing of sputum. These and the many unknown factors concerning the serums all contribute to the complexity of the problem. Perhaps the only redeeming feature in this respect has been the recent introduction of the use of rabbit serums, which are making available potent antibodies against most of the types. These products and the development of methods for their standardization may help to solve some of the problems.

What should be our present attitude? In the first place, every effort should be made to acquire the necessary basic information with regard to the frequency of the various types in pneumonia, the bacteremic incidence, the death rates among the various types of pneumonia and the occurrence of the same types of pneumococcus in the respiratory tract under other conditions. For this purpose the present resources may be utilized with only minor expansion. Our state laboratory and several other clinical and bacteriological laboratories are equipped to carry out complete typing of all pneumococci. It is highly desirable that all, or at least most, laboratories offering typing service be equipped to do likewise. The benefits from such a system accrue to all cases, particularly those actually caused by the more frequent and so-called "treatable" types. Errors, and particularly failures, in typing are much less likely to occur if it is required to ascertain the type of pneumococcus in a positive manner, rather than to report negative results when characteristic pneumococci are seen in a specimen and no reaction occurs with the four or five serums at hand. The work and expense entailed may be somewhat more than doubled (group serums are used first, and then the types within the positive group), but this is more than offset by the satisfaction of obtaining positive results on which to base a plan of action. To be sure, one may decide only to obtain another specimen and determine whether the "higher" type predominates, or whether another type is also present which can be identified. Frequently one of the commoner types is found, and may even predominate in the second specimen, particularly if better sputum is available. If this is the case, specific treatment is directed against the frequent type, since it is much more likely to be the causative organism.

The same argument applies, but with considerably greater force, to the advisability of using mouse inoculation\* to supplement direct typing whenever adequate numbers of pneumococci of the commoner types are not seen with the latter method. Examination of the peritoneal exudate of the mouse by the Neufeld method from three to six hours after the inoculation of such sputum or of the early growth from a throat culture will yield a homogeneous suspension of pneumococci with little extraneous material, this considerably diminishes the chances for errors and omissions.

Positive results of blood cultures are of the greatest help. Physicians have been repeatedly and urgently recommended to take frequent

The Massachusetts Department of Public Health is requiring laboratories approved for typing pneumococci to use either mouse inoculation or a satisfactory culture method to supplement direct Neufeld typing.

than four minutes, these periods being ten, eighteen and twenty minutes, respectively. In each of these patients rather large amounts of the drug had been administered. In no case was there any excessive sweating, as is so often seen with ethyl ether anesthesia. Postanesthetic vomiting occurred only five times. The impression was gained that vomiting may have been caused reflexly by collections of saliva in the pharynx during the recovery period, rather than by a central action of the drug.

#### PREMEDICATION

In the first few cases of the series, premedication was given with morphine and atropine. These were calculated for age and weight. It soon became evident, however, that premedication was not essential, and in most of the outpatient-department cases it was subsequently discontinued. Certainly morphine added little to the ease of induction and maintenance of the anesthesia. Atropine, however, while not necessary, diminished the incidence of excessive salivation, so that it was given in cases where it was anticipated that the operative procedure might be somewhat prolonged, it was employed in only one third of our cases.

#### SUMMARY

Vinyl ether (Vinethene) was employed as a

general anesthetic in a series of 100 infants and children ranging from one month to eleven years of age. This drug was extremely satisfactory for minor operative procedures, and in no case was there any alarming or untoward reaction accompanying or following the anesthesia. The extremely rapid induction period with this drug permitted full muscular relaxation in thirty or forty-five seconds. The period of recovery was likewise short, and in practically all cases the patient had regained consciousness in two or three minutes and older children were talking and sitting up by the end of this time. There was postanesthetic vomiting in only 5 cases.

Vinyl ether can be administered in a closed gas machine, mixing the vaporized drug with oxygen, but since the operation in which the anesthetic should be employed is a short one, this method of administration is somewhat cumbersome. The drug can be given easily and quickly on an open mask, and when thus employed in the present series was always satisfactory.

Vinyl ether appears to be the safest and most satisfactory general anesthetic yet produced for operative procedures of five or ten minutes' duration in infancy or childhood. The cost of the anesthetic is moderate, ranging from twenty-five to forty cents for an average case.

## THE USE OF SPECIFIC SERUMS IN THE TREATMENT OF PNEUMONIAS ASSOCIATED WITH PNEUMOCOCCI OF THE "HIGHER" TYPES\*

MAXWELL FINLAND, M.D.†

BOSTON

THE problem of the specific treatment of pneumonias due to the less frequent or "higher" types of pneumococci is a difficult one to discuss with any degree of finality at the present time. This can be easily appreciated when one considers that it took more than a quarter of a century to persuade any large body of physicians to use specific serums in cases of Type 1 pneumonia, in spite of the facts that this organism caused 30 per cent of all cases of primary lobar pneumonia and that an overwhelming body of experimental and clinical evidence supported the therapeutic efficacy of antipneumococcal serum in pneumonia due to this type.

It is best to consider the most frequent of the "higher" types, namely Types 5, 7 and 8, separately. Each of these is sufficiently prevalent so that significant numbers of cases may be accumulated within a reasonable time, enough to indicate the efficacy of any therapy. The data thus far available, both at the Boston City Hospital and elsewhere, already indicate the general character of the results attainable and the difficulties that may be expected. First of all, pneumonias due to the "higher" types may be quite atypical both in their symptomatology and in the character of the pulmonary lesions produced. This is in sharp contrast to Types 1 and 2, which are associated, except in rare cases, with typical lobar pneumonias. Thus a small percentage of cases of Type 5 pneumonia are atypical, but among those due to Types 7 and 8, particularly the latter, the disease may be atypical in a considerable proportion of cases.

## REPORT ON MEDICAL PROGRESS

### GASTROENTEROLOGY

CHESTER M. JONES, M.D.\*

BOSTON

RECENT studies in gastroenterology have been directed toward obtaining evidence of the correlation between the various parts of the nervous system and the digestive tract, or of a similar influence of the endocrine system on the processes of digestion. Little new has been added, however, that warrants comment in the present review. Certainly, animal experiments to date indicate that injuries in the brain may produce physiologic or anatomic changes in the stomach or intestines. The clinical observations of Oppner and Zimmerman<sup>1</sup> on esophageal, gastric or duodenal lesions in association with cerebral disease would seem to add suggestive confirmatory evidence to such a point of view. Further studies are needed, however, before a satisfactory understanding is obtained of the close relation between cerebral or emotional disturbances and gastrointestinal activity.

Mention should be made of the work of Sandweiss and his associates,<sup>2</sup> who carried out observations on the effect of the injection of anterior-pituitary-like hormone (Antuitrin-S) on the healing of ulcers in Mann-Williamson dogs. The work was inspired by the clinical observation that pregnancy appears to have a beneficial effect on peptic ulcer. Most of the animals treated with the gonadotropic substance failed at autopsy to show evidence of ulcers, or else showed microscopic evidence of healing if an ulcer had formed. The authors conclude rather cautiously that the injection of large amounts of the gonadotropic hormone may have been responsible for the favorable results. Such studies are of extreme importance, and it is to be hoped that proof may be forthcoming that the activity of the digestive tract may be controlled, under proper conditions, through specific hormonal therapy.

Investigations on the physiology of the small bowel have been continued by Abbott, Karr and Miller,<sup>3</sup> Groen<sup>4</sup> and others, but at the present time these are still principally of academic interest. That they will contribute knowledge of extreme practical importance is hardly to be questioned, but for the purposes of this review, they are alluded to merely to point out that continued and important progress is being made in this field of physiology.

#### DISEASES OF THE ESOPHAGUS

Clinical consideration of the esophagus has been largely limited to a renewed interest in the surgical treatment of esophageal carcinoma. In the past three years, seventeen successful resections of the thoracic esophagus have been performed for cancer, and the report of Adams and his collaborators<sup>5</sup> is of interest in this regard. They attacked the problem experimentally and attempted to develop a surgical method consistent with a reasonable prospect of success. Resection of as much as 10 cm of the thoracic esophagus with gastro-esophagostomy was successfully performed in more than half of thirteen experimental animals. The high degree of success attending their operations on dogs determined the authors to attempt a similar procedure in a patient. Operation was successfully performed, and the patient had an entirely uneventful convalescence. Garlock<sup>6</sup> also has reported three successful operations of a similar nature. These results are important in that they may eventually lead to a relatively safe standardized procedure that may be applied to what is usually considered to be an inoperable condition.

#### PEPTIC ULCER

The literature on peptic ulcer is voluminous and consists mainly in clinical reports and discussions of various therapeutic measures, but it is still obvious that an entirely satisfactory method of treatment remains to be found. One important paper is that of Crohn and Schwartzman,<sup>7</sup> who present an interesting study on ulcer recurrences associated with infections of the upper respiratory tract. The authors propose that the Schwartzman phenomenon is operative in such recurrences and believe that a state of reactivity is set up in patients with ulcer by secondary bacterial invaders. Several examples of ulcer recurrence, especially with hemorrhage, are cited in association with intercurrent infection of the respiratory tract. Although this clinical observation is not new, the authors are wise in calling attention to the importance of the underlying mechanism and to the necessity for special care in the treatment of patients with ulcer during such infections. Other clinical observations of some importance are those of Mixer<sup>8</sup> and Jones,<sup>9</sup> who report cases of ulcer of the posterior wall of the duo-

\*Assistant professor of medicine, Harvard Medical School; physician, Massachusetts General Hospital.

blood cultures during the acute stage of pneumonia. The results of such cultures are the best available guides to proper diagnosis and prognosis and the conduct of serum therapy, and serve as the best safeguard for the interpretation of the results of the typing of sputum. In any patient with pneumonia, the discovery in the blood culture of a growth of pneumococci which are identified with any of the "higher" types is the best available indication for specific treatment, provided serum for that type can be obtained. The probable mortality in bacteremic cases is extremely high without serum, and specific antibody offers perhaps the best hope of obtaining a cure.

In cases with sterile blood cultures, or before the results are available, it is best to consider all the facts at hand. The severity of the disease, the age of the patient, the character of the material from which the sputum was obtained, the number of organisms of that type seen and the relative number and character of other organisms present (as seen in the Neufeld preparation and in a gram-stained smear) will all influence the decision. If an infrequent type, or a common mouth inhabitant, such as Type 3 or Type 6, is obtained in small numbers from a poor specimen, or if other organisms predominate, it is best to obtain a second and better specimen in order to ascertain the relative numbers of the pneumococcus in question. At times, if part of the same specimen is sent to a second laboratory, it may be discovered that a common type was missed owing to errors in technique or interpretation or to deterioration of the typing serum. In acutely sick patients with good sputum raised from the bronchi, particularly if it

is rusty, the discovery of a given type as the only or definitely predominating organism is adequate indication for specific serum, and its proper employment will probably increase the chances of rapid recovery.

Further experience may reveal that certain of the types are more regularly and intimately related to pneumonia than are others. Already it appears that a greater proportion of Types 4, 12 and 18 pneumococci, for example, are causative agents in pneumonia than are those of Types 6, 10, 20 and types "higher" than Type 20. This is only relatively true, however, since probably every type may cause severe and even fatal pneumonia under the proper circumstances or in a particular individual.

What has been said refers to the employment of specific serums. As for the use of the newer chemotherapeutic agents, their field of usefulness has not been thoroughly explored. There are so many difficulties and even dangers associated with their use, and the data concerning the exact limits of their value are so inadequate, that one is justified in refraining from utilizing them in cases of pneumonia except under ideally controlled conditions. Exact clinical and bacteriological studies, including blood cultures, and the complete typing of pneumococci and even cultures of sputums, should be made in order to be able to define the merit of such agents or to detect the conditions under which they fail, and in order to be prepared to cope with such conditions. Such data, obtained at the earliest moment, will place the physician in a position to use specific serum as soon as it becomes apparent that the patient is not responding to or cannot tolerate the chemotherapeutic agent.

who were treated with the drug. It is still too early to evaluate the results of such medication as that reported by Metz and Lackey, but at present one should be content to regard this latest addition to the treatment of ulcer as an interesting attempt to correlate certain known physiological facts with the manifestations of a chronic disease.

The question of surgical measures in relation to peptic ulcer and its complications still raises many controversial points of view. It is obvious that the ideal operation applicable to the ulcer patient is still a matter of individual opinion, which ranges between rather wide extremes. For the most part, surgeons lean toward a conservative type of surgery in the treatment of perforated ulcer, although many Continental surgeons advocate subtotal gastrectomy as the method of choice. A similar divergence of opinion exists in a consideration of the immediate treatment in cases with massive hemorrhage from ulcer. Not only is there no unanimity of opinion regarding surgical intervention, but even in those cases in which surgery seems to be indicated there is a wide discrepancy between those advocating relatively simple surgery and those demanding subtotal removal of the stomach as the only logical procedure. In this country, for the most part, the conservative measures seem to be more favorably considered than are the extreme ones. Reference to various articles that have appeared during the year does little to clear up the confusion arising from these divergent views, but it is worth while to suggest the soundness of the opinion expressed by Cutler,<sup>17</sup> who comments on the type of operation to be employed in cases where surgery is indicated. In a review of the surgically treated patients at the Roosevelt Hospital between the years 1934 and 1937, he states that the following guiding principles in the choice of operation have been evolved: (1) the operation must be of such a nature that the particular patient can tolerate and survive it, (2) not only should it aim at the alleviation of symptoms, but it should give freedom from the likelihood of complications, both early and late, and (3) the ideal operation having been determined, it should be abandoned if the lesion found so indicates. One might add as a fourth desideratum that in deciding for or against surgery in such patients, the final conclusion should rest on a balancing of risks, namely the risk of operation as opposed to the risk of a continuation of non-surgical measures.

A renewed interest in the optimal treatment for the ulcer patient suffering from massive hemorrhage can be observed in the literature for the last two years, and as indicated above, there is a wide divergence of opinion as to therapeutic

measures. There can be little doubt, however, that the experience of most observers warrants one in assuming that the patient should be treated by careful medical measures except on rare occasions. Certainly in the group of patients under fifty years of age, conservative measures are indicated, and the application of detailed treatment similar to that advocated by Meulengracht usually gives good results. There is no doubt that we have definitely withdrawn from a policy of withholding food from a patient with a bleeding ulcer, although it still may be wise to accept Meulengracht's very liberal regime with some reservations. There is also no doubt, however, that occasionally in the younger group and certainly among those patients over the age of fifty, surgical measures must be resorted to in order to save the lives of individual patients. It should be a matter of routine for both the physician and the surgeon to see patients suffering from massive hemorrhage, in order to arrive at an early and correct decision in individual cases. Two excellent epitomes<sup>18</sup> of this somewhat troublesome problem are well worth reading. In the final analysis, no routine procedure will constitute a satisfactory approach in every case, but in each instance it should be a matter for individual decision.

Another point that has received much attention is the question of vitamin C deficiency in the disease under discussion. Without reference to specific articles, it is sufficient to comment on the fact that, according to present standards, vitamin C deficiency is the rule rather than the exception in patients with ulcer. It is in no way specific of the disease, but is common in many cases where dietary limitation or emaciation exists. As yet there is no evidence that vitamin C lack has any absolute etiologic importance in the causation of the disease, nor has any proof been brought forward up to the present time that the administration of vitamin C is of other than general importance in patients with ulcer. The particular exception to this statement may be found in the suggestion that in patients requiring surgical procedures, vitamin C lack should be treated adequately in order to provide for proper healing and an uneventful convalescence.

Any consideration of the problem of ulcer should include a comment on the complication of perforation. Although the idea is not in any way new, an interesting diagnostic comment is found in the studies by Paune and Rigler,<sup>19</sup> who made observations on 13 patients incidental to the production of diagnostic pneumoperitoneum. They demonstrated on these patients, as well as on 5 cadavers, that at times as small a quantity of gas as 5 cc could be demonstrated roentgenologi-

denum in which pain in the back was the sole or predominating symptom. These cases are of especial interest inasmuch as they are usually seen as orthopedic or neurological problems until some complication, such as hematemesis, makes it apparent that an ulcer exists.

Modifications in the treatment of ulcers fall under two headings—medical and surgical. Of the former, the majority, as usual, are concerned with the employment of measures directed toward reducing gastric acidity. The use of aluminum hydroxide gel has been reviewed by Emery and Rutherford<sup>10</sup> and Beazell, Schmidt and Ivy,<sup>11</sup> among others. The former, in using this preparation, have found that the symptoms of ulcer appear to be readily relieved by its administration, without any interference with the acid-base balance. There appears to be slight absorption from the gastrointestinal tract, but undoubtedly this preparation avoids all danger of producing alkalosis. They at first employed the drip method suggested by Woldman, but subsequently found that the oral administration of the drug was efficacious. This is of some importance inasmuch as it simplifies the entire procedure for the average patient, and it is quite probable that the drip method of treating ulcer should be limited to those patients who fail to respond to ordinary measures. Ivy and his associates were unable to produce evidence that aluminum hydroxide interfered with absorption in the gastrointestinal tract.

Further reports on the use of magnesium trisilicate by Tidmarsh and Baxter<sup>12</sup> indicate that it is a useful preparation which aims at neutralizing or absorbing gastric acidity without altering the pH of the blood. These authors added atropine and phenobarbital to the magnesium trisilicate and found the preparation of value in that it brought about restful nights, lack of apprehension and normal intestinal function. An ingenious combination of dried milk and calcium carbonate has been devised by Wosika<sup>13</sup> and consists in compressed tablets, combining the advantages of milk feedings and the use of alkali. The chief asset of the preparation is its small bulk, which makes it possible for the patient to carry the tablets in his pocket.

Several attempts have been made to control the symptoms of ulcer by the use of bile or bile acids, with varying success. The best recent estimate of this form of therapy is that of Emery and Schnitzer,<sup>14</sup> who treated a group of 40 patients with desiccated ox bile over periods of two years. The basis of such treatment lies in the fact that the diversion of bile from the duodenum in animals is an important detail in the experi-

mental production of ulcer. In the group of patients that were treated with adequate doses of ox bile, a satisfactory relief of symptoms occurred in approximately half the cases, a proportion that is not much better than that of spontaneous cures, as the authors aptly remark. They also conclude that the results seem to rule out disturbances in biliary secretion as a cause of peptic ulcer in man. The above measures, in reality, represent no radical departure from accepted methods of treatment, but differ only in the details of attempting to reduce gastric acidity by medicinal preparations.

In view of the publicity in the lay press attached to the treatment of ulcer with posterior pituitary extract, as reported by Metz and Lackey,<sup>15</sup> it is important to comment on their work. Several investigations have been carried out since the original studies by Hess in 1920 on the influence of hypophysial extract on gastric secretion, and a preliminary report on the use of posterior pituitary extract in the treatment of ulcer was presented by Metz and Lackey<sup>16</sup> in 1937. In the recent report, observations were made on 28 individuals suffering from peptic ulcer. Complete symptomatic relief was obtained in 24 patients within three weeks following the administration of a fresh preparation of the posterior pituitary gland, administered hypodermically, orally or intranasally. The latter route was preferred because of the absence of undesirable side-effects and because of the more certain utilization of the drug. The authors advance the hypothesis that many patients with peptic ulcer exhibit symptoms of pituitary deficiency, an assumption based largely on the fact that 15 of their patients had definite polyuria and nocturia which responded more or less successfully to the treatment. They further state "Recurrences of ulcer healed under pituitary administration are to be expected, since this therapeutic agent probably relieves temporarily a deficiency." As further support of their theory, they report that they were able to confirm the findings of Dodds and others to the effect that pituitrin increases the secretion of gastric juice in dogs following stimulation with histamine. The subjective relief of the symptoms of ulcer by the intranasal insufflation of posterior pituitary extract would thus seem to add another method to our armamentarium. One is forced to recall the fact, however, that almost any striking method of treatment of peptic ulcer has always been associated with transient benefit. In this respect, it is important to recall the experiments of Sandweiss and others on the parenteral injection of histidine, during which it was found that control patients treated with sterile solutions of physiological saline were benefited as readily as those

who were treated with the drug. It is still too early to evaluate the results of such medication as that reported by Metz and Lackey, but at present one should be content to regard this latest addition to the treatment of ulcer as an interesting attempt to correlate certain known physiological facts with the manifestations of a chronic disease.

The question of surgical measures in relation to peptic ulcer and its complications still raises many controversial points of view. It is obvious that the ideal operation applicable to the ulcer patient is still a matter of individual opinion, which ranges between rather wide extremes. For the most part, surgeons lean toward a conservative type of surgery in the treatment of perforated ulcer, although many Continental surgeons advocate subtotal gastrectomy as the method of choice. A similar divergence of opinion exists in a consideration of the immediate treatment in cases with massive hemorrhage from ulcer. Not only is there no unanimity of opinion regarding surgical intervention, but even in those cases in which surgery seems to be indicated there is a wide discrepancy between those advocating relatively simple surgery and those demanding subtotal removal of the stomach as the only logical procedure. In this country, for the most part, the conservative measures seem to be more favorably considered than are the extreme ones. Reference to various articles that have appeared during the year does little to clear up the confusion arising from these divergent views, but it is worth while to suggest the soundness of the opinion expressed by Cutler,<sup>17</sup> who comments on the type of operation to be employed in cases where surgery is indicated. In a review of the surgically treated patients at the Roosevelt Hospital between the years 1934 and 1937, he states that the following guiding principles in the choice of operation have been evolved: (1) the operation must be of such a nature that the particular patient can tolerate and survive it, (2) not only should it aim at the alleviation of symptoms, but it should give freedom from the likelihood of complications, both early and late, and (3) the ideal operation having been determined, it should be abandoned if the lesion found so indicates. One might add as a fourth desideratum that in deciding for or against surgery in such patients, the final conclusion should rest on a balancing of risks, namely the risk of operation as opposed to the risk of a continuation of non-surgical measures.

A renewed interest in the optimal treatment for the ulcer patient suffering from massive hemorrhage can be observed in the literature for the last two years, and as indicated above, there is a wide divergence of opinion as to therapeutic

measures. There can be little doubt, however, that the experience of most observers warrants one in assuming that the patient should be treated by careful medical measures except on rare occasions. Certainly in the group of patients under fifty years of age, conservative measures are indicated, and the application of detailed treatment similar to that advocated by Meulengracht usually gives good results. There is no doubt that we have definitely withdrawn from a policy of withholding food from a patient with a bleeding ulcer, although it still may be wise to accept Meulengracht's very liberal regime with some reservations. There is also no doubt, however, that occasionally in the younger group and certainly among those patients over the age of fifty, surgical measures must be resorted to in order to save the lives of individual patients. It should be a matter of routine for both the physician and the surgeon to see patients suffering from massive hemorrhage, in order to arrive at an early and correct decision in individual cases. Two excellent epitomes<sup>18</sup> of this somewhat troublesome problem are well worth reading. In the final analysis, no routine procedure will constitute a satisfactory approach in every case, but in each instance it should be a matter for individual decision.

Another point that has received much attention is the question of vitamin C deficiency in the disease under discussion. Without reference to specific articles, it is sufficient to comment on the fact that, according to present standards, vitamin C deficiency is the rule rather than the exception in patients with ulcer. It is in no way specific of the disease, but is common in many cases where dietary limitation or emaciation exists. As yet there is no evidence that vitamin C lack has any absolute etiologic importance in the causation of the disease, nor has any proof been brought forward up to the present time that the administration of vitamin C is of other than general importance in patients with ulcer. The particular exception to this statement may be found in the suggestion that in patients requiring surgical procedures, vitamin C lack should be treated adequately in order to provide for proper healing and an uneventful convalescence.

Any consideration of the problem of ulcer should include a comment on the complication of perforation. Although the idea is not in any way new, an interesting diagnostic comment is found in the studies by Paine and Rigler,<sup>19</sup> who made observations on 13 patients incidental to the production of diagnostic pneumoperitoneum. They demonstrated on these patients, as well as on 5 cadavers, that at times as small a quantity of gas as 5 cc could be demonstrated roentgenologi-

cally in the right subphrenic space. In nearly one fifth of a series of 38 cases of perforation of the stomach or duodenum, free gas was observed by this method, and the suggestion of the authors that in doubtful cases a careful search for small, localized collections of gas under the diaphragm may be of real diagnostic value is a very pertinent one.

#### DISEASES OF THE ILEUM

An interesting clinical report on disease of the small bowel is found in an article by Wolpaw,<sup>20</sup> in which he describes 3 cases of ulcerative hyperplastic tuberculosis of the small intestine. Although this is occasionally a cause of intestinal obstruction, its rarity, together with the fact that, as a rule, it exists without any evidence of active pulmonary disease, makes the report of importance. This is particularly so because a reasonably early diagnosis of the condition may frequently be accompanied by successful surgical removal of the local lesion. Charr and Cohen<sup>21</sup> determined the incidence of intestinal tuberculosis in necropsy studies of patients dying from tuberculous anthracosis and in those who died of pulmonary tuberculosis without anthracotic involvement. The incidence of intestinal tuberculosis was approximately 50 per cent among the latter, whereas it occurred in only 20 per cent of the former. A review of the therapeutic aspects of the treatment of intestinal peritoneal tuberculosis is presented by Mayer and Dworkin,<sup>22</sup> who point out the excellent results frequently obtained by the cautious use of x-ray therapy and the enthusiastic use of ultraviolet therapy.

The frequent appearance of clinical articles on regional ileitis does little to clarify the situation so far as therapeutics is concerned. The clinical aspects of the condition are now fairly well recognized by the profession, and the increasing accuracy of x-ray visualization of the small bowel has contributed appreciably to diagnosis. The clinical variations in the course of the disease are becoming somewhat clearer, although at times one is led to wonder whether enough attention has been paid to the cyclic changes which are almost as typical of this condition as they are of idiopathic ulcerative colitis. To date, studies as to the etiology of the disease have been inconclusive. So far as the literature is concerned, surgical treatment has occupied the place of importance, and radical resection of the involved areas of the bowel is still the chosen method of many who are interested in the problem. Because of the suggestive clinical and experimental evidence that the disease originates in the mesenteric lymphatics, Mixer

and Starr<sup>23</sup> believe that the successful results following resection of the affected ileum depend primarily on a wide excision of the involved mesentery and its lymph nodes. They also think that failure to carry out this type of excision may bear a definite relation to the recurrences frequently observed after surgical treatment. A more conservative point of view is expressed by Kross,<sup>24</sup> who briefly reviews the results in 3 cases. In one case, only the appendix was removed, the diseased bowel being left undisturbed, in the second, treatment consisted of an enterostomy, and in the third, a side-tracking colostomy was performed. These cases had no recurrences during periods of five and a half, four and three quarters and one and a quarter years respectively. In the opinion of the reviewer, there is still room for grave doubt as to the efficacy and, frequently, as to the wisdom of surgical procedures in this disease, except for specific indications such as obstruction, fistula formation, and the like. There is little doubt that intensive general medical care in many instances comprises the only method necessary for restoration to comparatively complete health. At the present time too few cases have been followed over sufficiently long periods of time to warrant any conclusive opinions as to the value of either medical or surgical procedures.

The question of the amount of small bowel that can be safely resected is particularly pertinent to the subject of ileitis, and since the end of the nineteenth century various studies have appeared on food absorption in patients with portions of the bowel removed. West and his associates<sup>25</sup> present such a report, with studies on digestion and absorption in a man with but 90 cm of small intestine. This patient had had five resections of the small bowel performed over a period of eleven years, with less than 30 cm of jejunum remaining. At exploration, several months prior to the metabolic studies, the remaining small bowel was found to be dilated and hypertrophied almost to the size of the normal large intestine. It was found that under the existing conditions about 25 per cent of the ingested protein and 45 per cent of the fat were lost in the feces, representing roughly 25 per cent of the calorific value of the ingested food. Practically all the carbohydrate in the diet was absorbed and utilized. A high calcium and viosterol intake was necessary in order to keep the man in a positive calcium balance, and with what was apparently only about one sixth of the small bowel remaining, a fairly satisfactory existence was possible. Fat absorption appears to be the chief factor necessitating any

thing like the normal length of small bowel. The regulation of diet in this case may well be utilized as a guide to the dietary treatment of similar conditions.

#### APPENDICITIS

A survey of the literature for the year reveals an unusually large number of articles dealing with the subject of appendicitis. Renewed interest in this subject is obviously of importance in view of the general feeling that mortality from this disease is still unnecessarily high. The diagnostic and therapeutic aspects of the problem have been stressed. Flannery,<sup>28</sup> for example, after a study of the records of 440 cases, emphasizes two well-known but important points: the increased mortality following the administration of catharsis for acute abdominal symptoms, and the importance of deferring operation in those patients where a diffuse peritonitis is suspected. Collins,<sup>27</sup> in a review of over 3000 consecutive appendectomies, encountered 751 instances (25 per cent) of acute retrocecal appendicitis. He points out the difficulties of this diagnosis and again emphasizes the dangers attending the administration of laxatives. Of some interest is his discussion of the variation in the localization of pain experienced by various patients in this large group. One hundred and thirty-seven patients complained of epigastric or right hypochondriacal pain, without any localization at McBurney's point, 214 complained of right lumbar pain, 88 experienced pain in the right shoulder, and 107 had severe pain in the upper part of the abdomen which continued for over six hours. Only 142 patients presented the clinical signs of acute appendicitis. Correct preoperative diagnoses were made in only two thirds of the cases.

Bower and his associates<sup>28</sup> analyzed the causes of death in acute appendicitis and estimated that 92 per cent were due to peritonitis. Almost 90 per cent of those admitted to the hospital with spreading peritonitis had received one or more doses of laxatives. The mortality of the group was 115 per cent higher than that of the group who had not received aperients. The article is extremely critical in its survey of the treatment of the symptoms of those patients presenting localizing or spreading peritonitis.

The numerical importance of appendicitis among college students has received attention in recent years, and an illuminating article is that of Schmidt and Joachim,<sup>29</sup> who reported on 1303 cases of appendicitis encountered in students at the University of Wisconsin. Von Mikulicz-Radecki<sup>30</sup> investigated the relation between appendicitis and female

sterility. He considers that appendicitis is the cause of sterility in every seventh case and that it takes the third place among all the causes of this condition. He advisedly warns surgeons against drainage of Douglas's pouch and also against intervention in the uterine adnexa in the course of appendectomies. Låwen<sup>31</sup> discusses in rather interesting fashion the relation between what he termed in 1914 "fibroplastic appendicitis" and terminal or regional ileitis. Although the discussion involves rather arbitrarily the classification of various clinical and pathologic pictures, the article is of importance in that it calls attention to the not infrequently incorrect diagnosis of appendicitis in the presence of ileitis.

The question of the chronic appendix continues to receive consideration, but little if anything new of importance has been presented. An undoubtedly correct point of view is that of Swalm and Morrison,<sup>32</sup> who plead for a conservative attitude toward appendectomy for chronic appendicitis. They stress particularly the frequency with which this condition is incorrectly diagnosed in the presence of a spastic, irritable or unstable colon. Reference should also be made to a thoughtful study by Shelley<sup>33</sup> of 881 cases of "chronic appendicitis." Shelley believes that he has adequate evidence that such a clinical entity exists, but emphasizes the extreme importance that should be attached to a definite localization of physical findings and to the nature and frequency of attacks. Although presenting an obviously surgical point of view, the author is extremely careful to insist on the utmost diagnostic care in ruling out other conditions simulating appendicitis. The article is well worthy of careful perusal.

#### INTESTINAL OBSTRUCTION

Intestinal obstruction continues to be of interest from the point of view of investigation and treatment. Numerous contributions on the use of Wangensteen decompression or drainage by the Abbott-Miller tube are of interest but present little that is new. Proponents of these methods frequently stress the value of such procedures without calling attention to the difficulties attending their use.

Although there is little, if anything, new regarding x-ray diagnosis of complete or partial intestinal obstruction, the importance of this diagnostic procedure is very properly emphasized by Solis Cohen and Levine.<sup>34</sup> They stress the extreme diagnostic importance of flat or survey films of the abdomen in the early stages of acute intestinal obstruction and the need for examining patients

in the prone, supine and upright positions. With other roentgenologists, they agree that the absence of a step-ladder appearance does not rule out an ileus and indicate that they consider the appearance of trapped gas and hairpin turns as among the earliest signs of acute intestinal obstruction. Although it is true that there may be an over-emphasis on such diagnostic procedures to the detriment of an ordinary careful physical examination, it is equally true that many physicians are still unaware of the diagnostic help that can be obtained from the roentgenologist in this serious condition. Excellent illustrations accompany the article.

The diagnosis and treatment of intussusception by non-surgical means has received considerable attention. Björkroth<sup>35</sup> stresses the diagnostic as well as the therapeutic value of the opaque enema. In recent years the good results obtained by manipulative and surgical means are due to early diagnosis. The partial disinvagination brought about by an opaque enema makes subsequent surgical correction easier. Povlsen,<sup>36</sup> in reporting on a case of intestinal invagination, also emphasizes the therapeutic value of long-continued high enemas, with bloodless reposition of the bowel under roentgen control. A similar report, given in somewhat more detail, is that of Orfila and his collaborators.<sup>37</sup> These authors report the successful treatment of 10 cases of intussusception occurring in infants and children ranging from three months to four years in age. Under barium enemas, usually given without anesthesia, and under roentgen control, disinvagination generally took place, as evidenced by the passage of barium into the ileum. All types of intussusception in the ileum may be reduced by barium enema and roentgen control, the only contraindication being that of a late diagnosis.

#### ULCERATIVE COLITIS

The subject of ulcerative colitis, as usual, has received a good deal of attention. It is becoming apparent that the nature and history of the disease are more clearly understood than they were in recent years. Its etiology is still unknown, although various workers have attempted to find the causative organism. There is nearly complete agreement that the diplostreptococcus of Bergen is at best a secondary invader, and attempts to prove that *Shigella dysenteriae* is a responsible agent are still far from convincing. A very excellent symposium on the entire subject was presented by Mackie,<sup>38</sup> T. E. Jones<sup>39</sup> and Willard and his associates.<sup>40</sup> In these three articles the question of therapy is well covered from the points of view of both the medical and the surgical ap-

proach. A perusal of the three papers and the discussions in this symposium will be of real value to anyone interested in this disease—a malady which presents one of the most difficult therapeutic problems of the day. The conclusions in Mackie's paper may well be quoted:

Chronic ulcerative colitis appears to be the complex expression of the interaction of several different factors. The disease exhibits an inherent tendency to progression and relapse. Although the prognosis under medical management is good in the pathologically mild and moderately advanced case, the term 'apparently arrested' should be substituted for 'cured.' Prolonged joint medical and surgical observation is essential for the pathologically advanced case. Combined medical and radical surgical treatment offers the best prognosis for many of the pathologically advanced cases.

Jones comments on the extremely bad prognosis in the so-called fulminating form of the disease, a type that usually can be recognized by the curious velvety, diffusely oozing appearance of the rectum and rectosigmoid by sigmoidoscopy. Such cases, as a rule, respond very badly to either medical or surgical measures. Among other important points in the paper by Willard and his collaborators, attention is called to the fact that the extent of x-ray involvement does not constitute a reliable prognostic sign. One cannot escape the conviction that ileostomy and colectomy are the only surgical procedures of choice in an important group of patients suffering from ulcerative colitis. The reviewer would like to point out the absolute necessity for a very close correlation between medical and surgical management in these patients, who present all the extreme manifestations of deficiency disease and chronic infection.

One point of therapeutic interest is the appearance of articles on the use of sulfanilamide or sulfanilamide derivatives. With the widespread use of these preparations, it was to be expected, that a chronic disease of the clinical importance of ulcerative colitis would before long have been treated by sulfanilamide medication. The use of Neo-prontosil (di-methyl-di-sulfanilamide) on 12 cases of ulcerative colitis is made the basis of a preliminary report by Bannick and his associates<sup>41</sup> from the Mayo Clinic. Apparently in the milder cases there was a prompt subsidence of symptoms following the use of the drug, which suggested that it had been responsible for the clinical improvement. The authors recognize, however, the characteristic occurrence of spontaneous remissions and are extremely cautious in drawing any conclusions. They suggest that the drug may be useful in mild cases and that it may help bring about improvement in the underlying condition. Further studies with this particular therapeutic agent will be of extreme interest.

## AVITAMINOSIS

The relation between avitaminosis and disorders of the digestive tract continues to attract widespread interest, and numerous articles have appeared dealing with various phases of this subject. The relation of vitamin C deficiency to peptic ulcer and other disorders has already been commented upon. Two authoritative articles by Cowgill<sup>42</sup> should be read by all interested in the treatment of patients who are apparently suffering from lack of vitamin B<sub>1</sub>. In these articles Cowgill discusses the requirements of the normal adult and child, mother and infant, and pays particular attention to the loss of vitamin B<sub>1</sub> through excretory channels. This last consideration is of extreme importance from the point of view of the widespread therapeutic use of crystalline vitamin B<sub>1</sub>. Not only is there an appreciable loss of this substance in the presence of pronounced diuresis, but also as a result of diarrhea. In patients suffering from diarrhea, evidence of the lack of this vitamin is frequently noted, and Cowgill's suggestion that the adequate administration of vitamin B<sub>1</sub> can be obtained only by parenteral use is timely and important.

Further observations on the value of nicotinic acid have appeared during the year. Of these, the most important are those of Spies and his collaborators,<sup>43</sup> together with a similar article by Matthews.<sup>44</sup> All these observers agree as to the remarkable efficacy of nicotinic acid in the treatment of pellagrous glossitis, stomatitis, vaginitis, urethritis and proctitis. Its effect seems to be more marked on these conditions than on the neurologic symptoms of the disease. Vilter, Bean and Spies, in one of the articles cited above, attempted to substitute dimethyl dinicotinic or dinicotinic acid for the original preparation in severely ill pellagrins. The physiologic response to these drugs was quite different, in that the flushing reaction and a rising cutaneous temperature did not occur, but these two drugs had only a partially beneficial effect on the symptoms of pellagra, and the authors believe that neither should be utilized as a substitute for nicotinic acid. They also stress the fact that protein deficiency in pellagra is of more importance than is currently supposed.

## GASTROSCOPY

The most important addition to our methods for the diagnosis of disease of the stomach—gastroscopy—has been thoroughly reviewed during the past year. Few, if any, new observations have been added to the large number already made by Schindler, Benedict and numerous others. A comprehensive summary of the entire subject, com-

menting on the role of gastroscopy in the recognition and identification of lesions, has recently been presented by Schindler<sup>45</sup> and constitutes an authoritative article for those interested in this extremely important subject. There is little doubt that this procedure has already made possible careful studies of gastritis, a condition that for some time has been misunderstood and improperly diagnosed. The causes of previously unexplained hemorrhage from the stomach can undoubtedly be visualized by the use of the gastroscope, and with the accumulation of sufficient observations on normal and abnormal stomachs, the relation between various forms of gastric irritation and gastric symptoms will become much more clear. That gastroscopy will ever prove the final arbiter in a differential diagnosis between benign and malignant lesions of the stomach in difficult cases is to be greatly doubted.

## CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTEMORTEM AND POSTMORTEM RECORDS AS USED  
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT, M.D.

TRACY B. MALLORY, M.D., *Editor*

### CASE 25081

#### PRESENTATION OF CASE

*First Admission* A sixty-year-old married, American railroad inspector was admitted complaining of nausea, vomiting and weakness of three hours' duration.

On the afternoon of entry the patient had a very sudden onset of weakness and faintness followed by nausea and vomiting. The vomitus consisted of recently eaten food. He had had such attacks occasionally since childhood. During the past two years he had been having attacks of palpitation and weakness with substernal pressure, relieved by lying down. One year before admission a consultant advised digitalis, which was used for a while and stopped because no evidence of cardiovascular disease, other than arteriosclerosis, could be found by the patient's physician. He soon began to feel under par and resumed the use of digitalis. There was never edema or any other sign of cardiac decompensation.

His father had died at fifty-seven of Bright's disease. One brother had had a "shock" ten years previously, after which he remained paralyzed. His past and family histories were otherwise non-contributory.

Physical examination showed a large, slightly cyanotic, restless man. The heart was not enlarged. There was a moderately sharp first sound, and a systolic murmur at the apex which obliterated the second sound. A diastolic murmur was heard at the base, most marked to the left of the sternum. There was an occasional dropped beat. The blood pressure was 80 systolic, 60 diastolic. The remainder of the physical examination was essentially negative.

The temperature was 100°F, the pulse 90, and the respirations 20.

The urine examination showed a green test with Benedict's solution, a positive diacetic acid test, a negative acetone test, and 2 to 4 white cells and many hyaline casts per high-power field. The blood showed a red-cell count of 5,400,000 and a white-cell count of 11,200. A blood Hinton test was negative. The fasting blood sugar was 111 mg per cent. An electrocardiogram showed a normal rhythm, a rate of 70, diphasic T waves in

all leads, a slurred QRS and left-axis deviation. X-ray films showed a small diverticulum on the left side of the lower end of the esophagus, just above the hiatus. The remainder of the gastrointestinal series and a barium-enema examination were negative. The kidney outlines appeared normal.

The patient's blood pressure returned to 125 systolic, 75 diastolic, on the second hospital day. A second-stage gastric diet, tincture of belladonna, phenobarbital and Amytal were prescribed and the patient rapidly improved. He was discharged on the eighth hospital day.

*Final Admission* (four years and eight months later) About a year before readmission the patient began to lose weight. Four months later he was advised to stop work because of shortness of breath, loss of energy and malaise. Six months before entry he had gained strength, his appetite had improved, and he was able to walk three miles some days with very little shortness of breath. He returned to work three months before admission but was forced to stop after three weeks when nausea, loss of appetite and dyspnea developed. He vomited almost daily during the following month. Two months before entry he vomited a tumblerful of blood, but none since. Marked weakness developed, and he lost his appetite completely. His stools remained normal. He had been taking digitalis and kept on until five days before entry. At this time he developed a marked tachycardia, — about 180, — and quinidine was given in full dosage for three days with slowing of the pulse rate. A year before admission he weighed 170 pounds, at the time of entry, 140 pounds.

Physical examination showed dehydration, emaciation and weakness, as well as slight jaundice. The heart was enlarged. There was an early blowing diastolic murmur best heard at the apex. The apical systolic murmur was high pitched. The aortic systolic murmur was rather rough.  $A_2$  was diminished. The blood pressure was 90 systolic, 60 diastolic. The lungs were clear. There was tenderness in the right upper quadrant of the abdomen, with voluntary spasm. The liver edge was palpable 2 cm below the right costal margin. There was slight edema of the thighs and feet.

The temperature was 100°F, the pulse 80, and the respirations 24.

The urine examination showed a trace of albumin and a specific gravity of 1.023, with many hyaline casts, a rare coarsely granular cast, a rare red cell and an occasional white cell per high-power field. It contained no sugar, bile, acetone or diacetic acid. The blood showed a red-cell

count of 5,400,000 with 90 per cent hemoglobin, and a white-cell count of 12,800 with 86 per cent polymorphonuclears. The nonprotein nitrogen of the serum was 72 mg per cent, the chlorides 106 milliequivalents, and the protein 6.4 gm per cent. A blood Hinton test was negative. A stool examination was negative. An electrocardiogram showed left bundle-branch block and partial A-V block. The P-R interval was 0.25 second.

X-ray films showed a normal esophagus. The upper gastrointestinal tract appeared normal.

On the fourth hospital day the patient was better, he did not vomit and was able to take some nourishment by mouth. On the fifth day there was edema of the right hand. Intravenous fluids had been given in the right arm, but there was no definite evidence of thrombophlebitis. Examination of the heart showed auricular fibrillation. The patient felt much better, but complained of nausea. An electrocardiogram at this time showed definite changes in the P waves and slight changes in T<sub>1</sub>, T<sub>2</sub> and T<sub>3</sub>. T<sub>1</sub> was inverted, T<sub>2</sub> diphasic, T<sub>4</sub> inverted, S-T<sub>1</sub>, S-T<sub>2</sub> and S-T<sub>4</sub> slightly low, S-T<sub>3</sub> slightly elevated. The QRS complex was slurred. P<sub>1</sub> was inverted, P<sub>2</sub> and P<sub>3</sub> diphasic. The P-R interval was 0.18-0.20 second. One day later the patient felt better. The liver seemed to be enlarged, and there was still definite jaundice. On the following day a van den Bergh showed 7.6 mg per cent of bilirubin. The lungs were clear.

During the next few days the patient seemed to lose ground. On the fourteenth hospital day his legs and thighs showed some increased edema. Itching of the skin was present, and few hemorrhagic blebs were seen on the hands and forearms. The hands were edematous. On the following day the patient was very weak. The lungs were clear, the heart and the edema unchanged. On the sixteenth day the patient was much worse. There were coarse rales at the right base. The liver seemed unchanged in size. During the previous two days the temperature had gradually risen to 105°F. Respirations rose to 50, the pulse to 140. The temperature had remained essentially normal since entry except for a rise to 101°F on the fifth day. The patient rapidly failed and died on the sixteenth hospital day.

#### DIFFERENTIAL DIAGNOSIS

DR. WYMAN RICHARDSON: I said not long ago that I had been caught too many times on a diagnosis of calcareous aortic stenosis and I am not going to be caught this time. I may be wrong, but "right off the reel" I am going to make that diagnosis. At least we can say that he certainly had heart disease, and the question is, Could this

whole picture be explained by heart disease or must we make some other diagnosis? As you know, on the basis of statistics Dr. Cabot always tried to make one diagnosis explain the whole story, but Dr. Mallory tells us that when dealing with old patients it is perhaps better to make as many diagnoses as we can to fit the symptoms.

To go over very briefly the first episode of rather sudden collapse, with vomiting and weakness, we are not helped at all by knowing that he had had such attacks occasionally since childhood. I shall point out that he had a diverticulum of the lower esophagus and possibly that might have accounted for them. It is known that patients with aortic stenosis of the calcareous type do have a variety of queer symptoms, and one sees not infrequently attacks of syncope and weakness of sudden onset coming out of a clear sky without prodromal symptoms. This whole first episode could be considered, I think, as a heart attack. The only question is, in view of the fact that later on he vomited blood, whether he had bleeding which was not recognized at that time. I considered this point but could not find any other evidence for it, so I am assuming that this attack of weakness was due to his heart. The description of the signs in the heart I shall not go over again, but he was known to have had a diastolic murmur of the aortic type and a loud systolic murmur said to have been heard better at the apex than at the aortic region.

In regard to the laboratory examination, I want to point out one thing—the positive test for diacetic acid. The diacetic acid test in this hospital presumably means the ferric chloride test for acetone bodies, and the acetone test refers to the sodium nitroprusside test. The latter test for acetone bodies is much more sensitive than the ferric chloride test. We should consider the positive diacetic acid test in this case to be a "false positive."

We have x-ray films of the gastrointestinal tract, and they are negative. One rather curious thing about this work-up is that nobody apparently was interested in taking an x-ray film of the heart.

The patient got along pretty well until about four years later and then another train of symptoms developed—weakness and weight loss, together with more vomiting than before, and dyspnea and signs that may be attributed to his heart failure. The physical examination was not very different, except for jaundice and a tender liver edge. The urine examination was consistent with passive congestion in the kidneys, with a fairly good specific gravity, and we do not have to as-

sume that he had renal failure to account for the edema and other symptoms

One interesting point in the laboratory findings is the blood chloride of 106 milliequivalents. He was probably somewhat dehydrated, but even so, one would expect with this amount of vomiting that his chlorides would have been lower than that. It does not help us any, but it leads one to suspect that he had an achlorhydria. The stool examination was negative as regards blood. I want to point out that there was no bile in the urine.

The patient failed rather rapidly. If you are going to try to make another diagnosis to cover such a lot of symptoms, there is nothing that points, so far as I am concerned, in any one direction, except that there was something that was affecting the liver to cause jaundice. If you are going to make such a diagnosis you have to refer to malignant disease of some sort. You can place it anywhere. You might have malignant disease of the pancreas with metastases to the liver. On the other hand, we know of patients with heart disease at this age and older who do lose a lot of weight because of heart disease—I presume because of congestion of the organs, and so forth. The electrocardiogram I have left strictly alone. Perhaps someone will comment on it later. To me, it means that there was considerable involvement of the heart.

I am going to say that this man's primary difficulty was heart disease, that he had calcareous aortic stenosis with some regurgitation and that he also had involvement of the coronary vessels, perhaps at their orifice, with consequent myocardial damage. In my experience these patients have rather bizarre symptoms, with dyspnea as a prominent feature, and once they begin to be dyspneic, they do not respond to the usual cardiac drugs or measures of treatment. Then, I am going to say that he had passive congestion of the liver. I am not going to talk about cardiac cirrhosis of the liver, and I see no reason to suppose that he had any other kind of cirrhosis. I am not going to talk about other types of liver disease. I am going to say that he had passive congestion of the kidneys and, finally, that he died with a local disease in the lungs. He probably had a terminal bronchopneumonia because the signs appeared localized on one side and were followed by a rapid rise in temperature. Whether we have to think of the question of emboli or pulmonary infarcts, I do not know, but I am going to leave that alone too. If there are x-ray films of the chest I think it would be fair to see them.

DR. TRACY B. MALLORY: None were taken during life.

DR. RICHARDSON: If one had been taken you might have been able to see the aortic valve.

DR. AUBREY O. HAMPTON: I have a postmortem film of the chest. I should like to know what might have happened if you had seen it, because a round mass at the right base is very interesting. His heart does look enlarged. This film is not good enough to show a calcified heart valve. There was motion in the lateral view even though the patient was dead. The round mass in the lung looks as though it might be due to malignancy.

A PHYSICIAN: Why is it not neurofibroma?

DR. HAMPTON: It is in the lung parenchyma.

DR. RICHARDSON: This is a postmortem film?

DR. HAMPTON: Yes. The heart shows, as you have predicted, the shape of one associated with aortic stenosis.

DR. MALLORY: There was one thing that struck me in reading over the record—the repeated comment about how dehydrated he was in spite of the fact that he was waterlogged. Is that an unusual combination in heart disease?

DR. RICHARDSON: I should think that might occur in any chronic edema.

DR. WILFRID J. COMEAU: Clinically this patient did not give the picture of heart failure. He was very weak and markedly dehydrated when he entered the hospital. Both Dr. Paul D. White and I believed there was little clinical evidence on physical examination that he had any significant heart failure, although there was no question about his having heart disease. The picture which he presented clinically was more that of malignancy and, as I have said, he was very ill and little could be done in the way of extensive study. We hoped that he might improve following the administration of fluids, but he never really did lose his dehydration. The edema was certainly no more than moderate at the most. Dr. Chester M. Jones and Dr. Alfred Kranes saw him, and we all believed that there was intrinsic disease of the liver as the cause of his illness and that his cardiac condition was really incidental.

DR. WILLIAM B. BREED: I do not mean to be hypercritical in asking Dr. Comeau a question, but I wonder what he means by "the picture of malignancy." That is a fairly broad statement, and I just want to know what he means by it.

DR. COMEAU: I mean the clinical picture that one associates with terminal malignancy—loss of weight, marked asthenia, emaciation and dehydration.

DR. BREED: But not referable to any particular part of the body?

DR. COMEAU: That is right.

Of course there is the tumblerful of blood which he vomited to be explained. His jaundice

was definite, and there was no history, as we went back, that indicated much in the way of cardiac symptoms. The dyspnea was questionable. Six months before his last entry he was able to walk three miles a day without discomfort. His history from the beginning pointed to the gastrointestinal tract and, as I have said, he did not give the picture of cardiac failure. He had no orthopnea and no dyspnea, and I might add that his lungs were clear and that it was not until the last few days that he developed signs suggesting either infarct or a pneumonic process at the right base. This was coincident with the terminal rise in temperature.

DR ALFRED KRANES: I saw him a few days before death. He was somewhat stuporous and could not co-operate very well, but I was impressed more than anything else by an apparent increase in the size of the liver, a point which the history does not bring out. When I went over him the liver edge was easily palpable in the midline down to the umbilicus. I believed that if there ever was a large liver this was one. It was tender. He would grunt every time you palpated that region. He had definite jaundice, and at the time there was no evidence of heart failure, and no venous distention. Although examination of the lungs was unsatisfactory, I could not detect anything. I thought, too, that he had intrinsic liver disease and that the heart disease was incidental, playing no part in the picture. Just what the nature of the liver disease was, I did not know. I thought obstructive jaundice could be ruled out and that perhaps he had some form of cirrhosis with superimposed malignancy, possibly a primary neoplasm of the liver. The spleen, however, was not palpable.

#### CLINICAL DIAGNOSES

Aortic stenosis  
Carcinoma of liver  
Bronchopneumonia

#### DR RICHARDSON'S DIAGNOSES

Calcereous aortic stenosis  
Congestive failure  
Chronic passive congestion of liver and kidneys  
Terminal bronchopneumonia

#### ANATOMICAL DIAGNOSES

Rheumatic heart disease  
Endocarditis, chronic rheumatic, mitral and aortic, with aortic stenosis  
Cardiac hypertrophy and dilatation  
Pulmonary infarction, right lower lobe  
Thrombosis, right popliteal vein  
Jaundice

Chronic pancreatitis  
Acute duodenal ulcer  
Chronic passive congestion of liver  
Thrombosis of periprostatic veins

#### PATHOLOGICAL DISCUSSION

DR MALLORY: I think it is quite possible that this is one of the types of cases it is easier to diagnose from the record than in life. Certainly Dr Richardson's predictions were all very closely fulfilled. The primary difficulty was heart disease. His heart weighed 615 gm, and it was considerably dilated. He did have aortic stenosis, but he also had a very marked involvement of the mitral valve. This was of a peculiar character. I can remember only one other case like it. All the leaflets of the mitral valve and the chordae tendineae were markedly thickened, but they were not shortened, so that the lesion did not seem to produce any deformity of the valve. Nevertheless, the auricle behind that valve was greatly dilated. The liver seems to have been another of those gymnastic ones we meet so often in these clinics; it had crawled up to the costal margin again by the time we saw it. It showed a very marked grade of chronic passive congestion, with extensive central necrosis but no cardiac cirrhosis. There was a considerable grade of bile stasis. The kidneys, I should say, were negative except for chronic passive congestion. The ball that you saw in the postmortem chest film at the right base was a massive pulmonary infarct that occupied about two thirds of the right lower lobe.

DR HAMPTON: That is the first round one I have seen.

DR MALLORY: Any patient with a sufficient degree of cardiac failure can develop jaundice. It is well known that the one thing that characteristically brings out jaundice—sometimes severe jaundice—in cardiac patients is to develop a pulmonary infarct. Dr Richardson was on the right track in saying that the one essential lack in the clinical work-up was a chest film, although I am not sure it would have helped him in his interpretation.

DR HAMPTON: If we had had a lateral film that did not show motion it might have been of help. I have never seen a perfectly round shadow in the anteroposterior view which proved to be an infarct at postmortem.

A PHYSICIAN: How long had the infarct been there?

DR MALLORY: We estimated about ten days.

A PHYSICIAN: What was the source of the gastrointestinal bleeding?

DR MALLORY: I neglected to mention two things

There was a small duodenal ulcer which appeared to be rather active. There was also a moderate grade of what I think one must call chronic pancreatitis. There were many small foci of fat necrosis scattered throughout the pancreas, and a slight chronic inflammatory infiltration. It did not seem to have destroyed a large amount of pancreas, and whether it was severe enough to have played a significant part in his clinical picture, I do not know. It may well have had bearing on the severe loss of weight.

## CASE 25082

### PRESENTATION OF CASE

*First Admission* A fifty-five-year-old Swedish woman was admitted complaining of intermittent epigastric pain of six months' duration.

The pain often started on the right side, spreading to the left, and at times covered the entire upper abdomen. It was usually not severe, never very sharp, but was sometimes severe enough to make her "writhe." It lasted several hours to half a day, occasionally woke her at night, and occurred on an average of every three days. During the previous few months anorexia and nausea were present. Two weeks before admission she vomited for the first time, the vomitus containing greenish, bitter material but no blood. She also had a moderate amount of belching.

For several years she had been constipated, took many cathartics and passed hard, black stools. She had not been jaundiced. During the previous year she had lost 30 pounds in weight. Her father had died of cancer of the liver, her mother of a tumor of the stomach.

Physical examination was negative except for a loud systolic murmur over the cardiac apex, a blood pressure of 175 systolic, 90 diastolic, and a palpable liver edge about 3 cm below the right costal margin.

X-ray films of the chest and abdomen were negative except for slight arteriosclerosis of the aorta. Two stool examinations were guaiac negative.

No definite findings developed and the patient was discharged on the twelfth hospital day with the diagnoses of hypertensive heart disease, mild congestive heart failure and anxiety neurosis.

*Second Admission* (seven months later) She had been much worse since discharge, complaining of a dull, aching distended feeling in the epigastrium. Soda gave some relief by causing gaseous eructation. Three months before entry she came to the Out Patient Department complaining that she had had chills and epigastric pain radiating to the back. Fatty foods aggravated the distress.

A Graham test showed no filling of the gall bladder.

On entry physical examination was essentially the same as that of the last admission. On the seventh hospital day a thickened adherent gall bladder was removed. A stone was impacted in the cystic duct, and two rather large stones were found in the fundus. She had an uneventful convalescence and was discharged on the twenty-fourth hospital day.

*Third Admission* (three years later) She entered for slight vaginal bleeding of five months' duration. There were no gastrointestinal complaints. Physical examination showed a slightly enlarged heart and a systolic murmur heard at the apex and aortic area. The blood pressure was 190 systolic, 98 diastolic. A uterine curettage showed adenocarcinoma. On the thirty-second hospital day radium was inserted. She was discharged six days later.

*Fourth Admission* (seven and a half years later) Four or five years before the fourth admission she noted the gradual onset of left upper-quadrant, nonradiating pain, which was of a dull "gripping" nature. Accompanying this was a feeling of general malaise. The pain was intermittent, not associated with meals, and did not cause nausea or vomiting. There was no change in bowel habits. No chills, fever or jaundice occurred. One year later a similar pain seemed to be superimposed in the midepigastrium. During the previous two years she had noticed slight morning nausea, but no vomiting. At that time she first became aware of epigastric distention. This had no relation to meals, coming on at most any time during the day. She had lost 5 pounds in weight since her previous admission. A gastrointestinal x-ray series taken in the Out Patient Department two months before admission showed a 3 cm, non-ulcerated, barium-coated defect lying within the lumen of the fundus of the stomach. The remainder of the examination was negative. Three weeks later examination was repeated and showed a round, non-ulcerated mass about 4 cm in diameter which was attached to the stomach wall by what appeared to be a 4-cm base. She had had no recurrence of vaginal bleeding or pelvic symptoms.

Physical examination showed a slightly obese female, weighing 139 pounds, in no distress. The left border of the heart was 3 cm outside the midclavicular line. An aortic systolic murmur was heard. The blood pressure was 195 systolic, 98 diastolic. Abdominal examination was negative.

The temperature was 98.6°F, the pulse 85, and the respirations 24.

Examination of the urine was negative. The

was definite, and there was no history, as we went back, that indicated much in the way of cardiac symptoms. The dyspnea was questionable. Six months before his last entry he was able to walk three miles a day without discomfort. His history from the beginning pointed to the gastrointestinal tract and, as I have said, he did not give the picture of cardiac failure. He had no orthopnea and no dyspnea, and I might add that his lungs were clear and that it was not until the last few days that he developed signs suggesting either infarct or a pneumonic process at the right base. This was coincident with the terminal rise in temperature.

DR ALFRED KRANES: I saw him a few days before death. He was somewhat stuporous and could not co-operate very well, but I was impressed more than anything else by an apparent increase in the size of the liver, a point which the history does not bring out. When I went over him the liver edge was easily palpable in the midline down to the umbilicus. I believed that if there ever was a large liver this was one. It was tender. He would grunt every time you palpated that region. He had definite jaundice, and at the time there was no evidence of heart failure, and no venous distention. Although examination of the lungs was unsatisfactory, I could not detect anything. I thought, too, that he had intrinsic liver disease and that the heart disease was incidental, playing no part in the picture. Just what the nature of the liver disease was, I did not know. I thought obstructive jaundice could be ruled out and that perhaps he had some form of cirrhosis with superimposed malignancy, possibly a primary neoplasm of the liver. The spleen, however, was not palpable.

#### CLINICAL DIAGNOSES

Aortic stenosis  
Carcinoma of liver  
Bronchopneumonia

#### DR RICHARDSON'S DIAGNOSES

Calcereous aortic stenosis  
Congestive failure  
Chronic passive congestion of liver and kidneys  
Terminal bronchopneumonia

#### ANATOMICAL DIAGNOSES

Rheumatic heart disease  
Endocarditis, chronic rheumatic, mitral and aortic, with aortic stenosis  
Cardiac hypertrophy and dilatation  
Pulmonary infarction, right lower lobe  
Thrombosis, right popliteal vein  
Jaundice

Chronic pancreatitis  
Acute duodenal ulcer  
Chronic passive congestion of liver  
Thrombosis of periprostatic veins

#### PATHOLOGICAL DISCUSSION

DR MALLORY: I think it is quite possible that this is one of the types of cases it is easier to diagnose from the record than in life. Certainly Dr Richardson's predictions were all very closely fulfilled. The primary difficulty was heart disease. His heart weighed 615 gm, and it was considerably dilated. He did have aortic stenosis, but he also had a very marked involvement of the mitral valve. This was of a peculiar character. I can remember only one other case like it. All the leaflets of the mitral valve and the chordae tendineae were markedly thickened, but they were not shortened, so that the lesion did not seem to produce any deformity of the valve. Nevertheless, the auricle behind that valve was greatly dilated. The liver seems to have been another of those gymnastic ones we meet so often in these clinics—it had crawled up to the costal margin again by the time we saw it. It showed a very marked grade of chronic passive congestion, with extensive central necrosis but no cardiac cirrhosis. There was a considerable grade of bile stasis. The kidneys, I should say, were negative except for chronic passive congestion. The ball that you saw in the postmortem chest film at the right base was a massive pulmonary infarct that occupied about two thirds of the right lower lobe.

DR HAMPTON: That is the first round one I have seen.

DR MALLORY: Any patient with a sufficient degree of cardiac failure can develop jaundice. It is well known that the one thing that characteristically brings out jaundice—sometimes severe jaundice—in cardiac patients is to develop a pulmonary infarct. Dr Richardson was on the right track in saying that the one essential lack in the clinical work-up was a chest film, although I am not sure it would have helped him in his interpretation.

DR HAMPTON: If we had had a lateral film that did not show motion it might have been of help. I have never seen a perfectly round shadow in the anteroposterior view which proved to be an infarct at postmortem.

A PHYSICIAN: How long had the infarct been there?

DR MALLORY: We estimated about ten days.

A PHYSICIAN: What was the source of the gastrointestinal bleeding?

DR MALLORY: I neglected to mention two things

There was a small duodenal ulcer which appeared to be rather active. There was also a moderate grade of what I think one must call chronic pancreatitis. There were many small foci of fat necrosis scattered throughout the pancreas, and a slight chronic inflammatory infiltration. It did not seem to have destroyed a large amount of pancreas, and whether it was severe enough to have played a significant part in his clinical picture, I do not know. It may well have had bearing on the severe loss of weight.

## CASE 25082

### PRESENTATION OF CASE

*First Admission* A fifty-five-year-old Swedish woman was admitted complaining of intermittent epigastric pain of six months' duration.

The pain often started on the right side, spreading to the left, and at times covered the entire upper abdomen. It was usually not severe, never very sharp, but was sometimes severe enough to make her "writhe." It lasted several hours to half a day, occasionally woke her at night, and occurred on an average of every three days. During the previous few months anorexia and nausea were present. Two weeks before admission she vomited for the first time, the vomitus containing greenish, bitter material but no blood. She also had a moderate amount of belching.

For several years she had been constipated, took many cathartics and passed hard, black stools. She had not been jaundiced. During the previous year she had lost 30 pounds in weight. Her father had died of cancer of the liver, her mother of a tumor of the stomach.

Physical examination was negative except for a loud systolic murmur over the cardiac apex, a blood pressure of 175 systolic, 90 diastolic, and a palpable liver edge about 3 cm below the right costal margin.

X-ray films of the chest and abdomen were negative except for slight arteriosclerosis of the aorta. Two stool examinations were guaiac negative.

No definite findings developed and the patient was discharged on the twelfth hospital day with the diagnoses of hypertensive heart disease, mild congestive heart failure and anxiety neurosis.

*Second Admission* (seven months later) She had been much worse since discharge, complaining of a dull, aching distended feeling in the epigastrium. Soda gave some relief by causing gaseous eructation. Three months before entry she came to the Out Patient Department complaining that she had had chills and epigastric pain radiating to the back. Fatty foods aggravated the distress.

A Graham test showed no filling of the gall bladder.

On entry physical examination was essentially the same as that of the last admission. On the seventh hospital day a thickened adherent gall bladder was removed. A stone was impacted in the cystic duct, and two rather large stones were found in the fundus. She had an uneventful convalescence and was discharged on the twenty-fourth hospital day.

*Third Admission* (three years later) She entered for slight vaginal bleeding of five months' duration. There were no gastrointestinal complaints. Physical examination showed a slightly enlarged heart and a systolic murmur heard at the apex and aortic area. The blood pressure was 190 systolic, 98 diastolic. A uterine curettage showed adenocarcinoma. On the thirty-second hospital day radium was inserted. She was discharged six days later.

*Fourth Admission* (seven and a half years later) Four or five years before the fourth admission she noted the gradual onset of left upper-quadrant, nonradiating pain, which was of a dull "gripping" nature. Accompanying this was a feeling of general malaise. The pain was intermittent, not associated with meals, and did not cause nausea or vomiting. There was no change in bowel habits. No chills, fever or jaundice occurred. One year later a similar pain seemed to be superimposed in the midepigastrium. During the previous two years she had noticed slight morning nausea, but no vomiting. At that time she first became aware of epigastric distention. This had no relation to meals, coming on at most any time during the day. She had lost 5 pounds in weight since her previous admission. A gastrointestinal x-ray series taken in the Out Patient Department two months before admission showed a 3 cm, non-ulcerated, barium-coated defect lying within the lumen of the fundus of the stomach. The remainder of the examination was negative. Three weeks later examination was repeated and showed a round non-ulcerated mass about 4 cm in diameter which was attached to the stomach wall by what appeared to be a 4-cm base. She had had no recurrence of vaginal bleeding or pelvic symptoms.

Physical examination showed a slightly obese female, weighing 139 pounds, in no distress. The left border of the heart was 3 cm outside the midclavicular line. An aortic systolic murmur was heard. The blood pressure was 195 systolic, 98 diastolic. Abdominal examination was negative.

The temperature was 98.6°F., the pulse 85, and the respirations 24.

Examination of the urine was negative. The

Blood showed a red-cell count of 4,250,000 with 90 per cent hemoglobin, and a white-cell count of 6800 with 67 per cent polymorphonuclears, 23 per cent small lymphocytes, 5 per cent mononuclears and 2 per cent eosinophils. The nonprotein nitrogen of the serum was 25 mg per cent, the chlorides 106 milliequivalents, and the protein 7 gm per cent. A blood Hinton test was negative. A phenolsulfonephthalein kidney-function test was normal. A stool examination was guaiac negative.

Preceding a gastroscopic examination 5 cc of cloudy gastric secretion was obtained which contained no free hydrochloric acid. The gastroscope revealed a normal antrum and pylorus. The color of the mucosa was normal except for a 4-mm erosion in the upper part of the body on the posterior wall. No polyp could be demonstrated but part of the field, especially along the lesser curvature, was obscured by mucus.

On the eighth hospital day an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR ALLEN G BRAILEY: But little was learned about this patient at the time of the first admission. On the second admission the gall bladder was taken out, and very likely, the symptoms on the first admission were due to gall-bladder disease. Part of the trouble may have been that she was Swedish and an accurate history was hard to get. There was very little evidence that she had any degree of congestive failure. There was no dyspnea or edema, and one does not lose 30 pounds from mild congestive failure. She was discharged without much being done. I assume the x-ray films of the chest and abdomen were done as a matter of routine, and when no trace of stone was found, it was decided she had an anxiety neurosis.

She returned to the hospital seven months later and a typical history of chronic cholecystitis was elicited. The removal of the gall bladder apparently resulted in a cure of her gastrointestinal complaints.

I judge the adenocarcinoma found on the third admission was in the fundus of the uterus. I know very little about surgery of the uterus, but suppose that hysterectomy would have been the proper procedure. Perhaps she refused operation. It is true that radium is sometimes used instead of operation, and it may be they believed, in view of hypertension and other conditions present, that operation was best avoided. Even though I do not approve of it, the treatment seems to have been very effective because there was apparently no recurrence of the trouble.

Seven and a half years later she gave a story of atypical epigastric complaints—a certain amount of distention, discomfort, and so forth. It is striking that if you take the x-ray examination out of this account of her fourth admission there is very little left. Such a story of mild digestive complaints might well have been due to so-called “nervous indigestion” or to gastritis. The laboratory findings are normal. Apparently the bone of contention is what was the nature of the lesion or defect in the stomach. I should very much like to see the films. Where is the 4-cm base?

DR GEORGE W HOLMES: I cannot demonstrate it, and apparently they did not succeed in demonstrating it on the film. It was probably determined from fluoroscopic examination. I think we can say the lesion is intrinsic and not in the wall of the stomach, because of the character of the margin of the shadow. If this were anything like a leiomyoma in the wall of the stomach it would not have this type of margin. The statement that it was not ulcerated should be taken with a grain of salt. We might not have been able to demonstrate an ulcer, but it seems fairly certain that there is an actual lesion, a pedunculated tumor growing into the stomach. There is nothing to indicate here whether it is benign or malignant. It is not a hair ball or any loose object in the stomach but a lesion attached to the wall of the stomach. The fact that they failed to see it at gastroscopic examination is what you would expect, one cannot see that portion of the stomach.

DR BRAILEY: That is a great help. I was not sure from the report whether this thing had not moved around and I was not perfectly certain it was attached to the wall of the stomach. Dr Holmes assures us that it is so attached. It probably is a polypoid lesion of some sort.

DR HOLMES: I am basing my statement on the record, not on what I see in the film.

DR BRAILEY: You cannot tell from the film whether it was floating around?

DR HOLMES: No, except that it is in an unusual position for a foreign body. I think that we can accept the statement as given by the man who examined the patient.

DR BRAILEY: It is still a bit ambiguous to me. I cannot pursue this differential diagnosis very far. I do not believe the lesion has anything to do with her previous admissions. If she had a cancerous lesion of any sort it is interesting that she had no anemia and had lost no appreciable amount of weight, although such good health might not be inconsistent with a cancer that had not ulcerated or become necrotic. Except that she was of cancer age, there is no very good evidence

of malignancy I am inclined to suppose that the lesion was benign, and I am not wholly convinced that she had anything wrong with her stomach. I do not believe we can absolutely exclude a hair ball or something of that sort. If the tumor is benign, it is an adenoma or a polyp and, as Dr. Holmes pointed out, would not be seen by gastroscopy. It was probably not the cause of her symptoms.

DR. PAUL D. WHITE: I cannot understand why mild congestive heart failure was diagnosed on the first admission. I agree that it seems ridiculous in the absence of any story of dyspnea. You must have dyspnea first.

DR. TRACY B. MALLORY: There is nothing more in the full record to explain that diagnosis.

DR. GRANTLEY W. TAYLOR: Her symptoms in her final illness began within a year or two of the time she had carcinoma of the uterus treated by radium, and while metastases to the wall of the stomach are very unusual, we do occasionally see capricious metastases. The possibility that the lesion is metastatic seems to me to be worthy of consideration.

DR. BRAILEY: Is it not fair to suppose that in seven and a half years it would have become an ulcerated mass?

DR. TAYLOR: Yes, that is entirely reasonable.

DR. HOLMES: If you could accept the x-ray report that this is a pedunculated lesion, could it be a metastasis?

DR. TAYLOR: Probably not.

#### CLINICAL DIAGNOSIS

Tumor of stomach

#### DR. BRAILEY'S DIAGNOSIS

Benign gastric polyp or adenoma

#### ANATOMICAL DIAGNOSIS

Leiomyosarcoma of stomach

#### PATHOLOGICAL DISCUSSION

DR. MALLORY: This patient was explored by Dr. Richard H. Sweet, who could feel with some difficulty through the anterior surface of the stomach a tumor of the posterior wall close to the cardiac orifice. He was forced to open the stomach in order to visualize it and then found that he was dealing with a circumscribed sessile tumor which was firm, with no ulceration of the mucosa

over it, and had all the gross appearances of a benign tumor. He was faced with a choice of doing either a very local excision or a practically total gastrectomy, and thought it was wiser to do the former. The specimen which reached the laboratory proved to be a spindle-cell tumor apparently of smooth-muscle origin and of a rather borderline malignancy. It contained a small number of mitotic figures and a rare tumor giant cell, and our eventual diagnosis was leiomyosarcoma. These tumors when they get a little bigger are more or less regularly accompanied by ulceration of the overlying mucosa, probably because of interference with the blood supply. The ulceration is apt to penetrate deeply into the tumor and then burrow laterally, giving a very characteristic picture, but I do not remember having seen such an ulceration in tumors as small as this.

DR. RICHARD SCHATZKI: We have seen it in tumors even smaller. I remember one patient who had a small duodenal tumor with ulceration.

I am wondering if there can be any connection between the degree of malignancy and the stage at which ulceration occurs. Is not ulceration more likely in a malignant tumor than in a benign one?

DR. MALLORY: I should think so. The probabilities of inadequate blood supply and necrosis are certainly greater in the former.

DR. SCHATZKI: The tumor I spoke of was very malignant, and the patient died shortly after with extensive metastases.

DR. HOLMES: Is it not unusual for that type of tumor to be sessile?

DR. MALLORY: No. We have seen a number that were. They can be either pedunculated or sessile. They can project either into the lumen of the stomach or externally into the abdominal cavity, thus causing no deformity whatever of the lumen of the stomach.

DR. EDWARD B. BENEDICT: How many metastatic tumors of the stomach have you seen?

DR. MALLORY: I cannot at the moment think of any.

DR. BENEDICT: I never saw one. I wonder if anyone has.

DR. MALLORY: I have seen metastases in other parts of the gastrointestinal tract.

DR. SCHATZKI: Cancer of the breast has been reported to have metastasized to the stomach.

DR. MALLORY: I see no reason why it should not occur, but it certainly is uncommon.

blood showed a red-cell count of 4,250,000 with 90 per cent hemoglobin, and a white-cell count of 6800 with 67 per cent polymorphonuclears, 23 per cent small lymphocytes, 5 per cent mononuclears and 2 per cent eosinophils. ## ANNUAL REGISTRATION OF PHYSICIANS

AGAIN this year the Board of Registration in Medicine has introduced a bill providing for annual renewal of registration of physicians. The primary object seems to be to find out what physicians are practicing medicine each year in the Commonwealth and where they have their offices. Under the present system, a physician after registration may be lost so far as the Board is concerned. He is expected to notify the town clerk when he opens an office for practice but there is no way of finding out where he does practice if he fails to report. Having once reported, he may move from city to city without notifying the town clerk. It would seem to be a reasonable requirement that the public be enabled to find out through the Board of Registration in Medicine what licensed physicians are in practice and where they are located.

Why then has there been such vigorous opposition to the bill in the past, and why are some physicians still opposed to it? It is not possible to discuss all the reasons given, but an examination of the bill indicates that most of the objections are the product of fancy. For example, it has been claimed, if the bill becomes law, that the medical profession will be regimented, that the Board will be given inquisitorial powers so that the police will call on physicians for full information about their practice, that neglect to register will mean immediate suspension of the physician's license, that it will make possible the withholding of registration by the Board for reasons of personal pique.

There are two intelligible objections to the bill. The first one is to the taxing of physicians so that the State may employ its police power (in part) for detecting unlicensed physicians. In this connection it is pertinent to note that the Board of Registration in Medicine is created and acts under the police power of the State. But, if the bill would seriously reduce the number of unlicensed practitioners, most physicians would not object, and there are few well-informed physicians who object to the tax, whether it be one or two or three dollars. Theirs is the second objection, namely, that if the money once gets into the state treasury, they see little chance of getting it out for the work of the Board, and they fear it will be diverted for some other purpose. "Eternal vigilance is the price of liberty" and under this democratic form of government of ours a remedy is provided. When the budget of the Board of Registration in Medicine is before the Committee on Ways and Means, these physicians who are fearful of the division of the additional revenue should appear in support of the Board's requests. It means effort and is time-consuming. However, if no one ever makes representations, is it unfair to assume that no one really cares?

Annual registration of physicians is in force in a number of states and has been found to be very helpful. In Massachusetts it is required for a number of other boards. What is so peculiar about medicine here that the public is not justly entitled

to know each year who is registered as qualified to engage in the practice of this profession?

The recent vote by the Council of the Massachusetts Medical Society to place itself on record as favoring the bill is to be interpreted as a decision by a gradually increasing number of physicians that in spite of all that has been said against annual registration and in spite of some slight cost and very slight inconvenience to themselves in filing the information required, the carrying out of the provisions of the bill will redound to the benefit of the public. This is, after all, the calculated purpose of the measure, and it is in accordance with the age-long efforts and the enduring spirit of the medical profession

---

### SCHOOLS FOR TECHNICIANS

THE marked development of the laboratory side of medicine has created a demand for workers who supplement the physician in his investigations in this field. These so-called technicians, some of whom have a very high degree of special knowledge and skill, carry on many of the procedures which lead to the establishment of certain facts. These facts are not the diagnosis but they are a part of the evidence which the physician reviews and interprets in making his diagnosis. Under former conditions each laboratory might train its own workers but the present demand has so far outrun the supply that special schools for technicians have been established.

Recent newspaper reports indicate that such a school for technicians was opened in Boston under auspices which were at least unfavorable. Efforts had been made to secure reputable and competent physicians as teachers, but soon the school passed into the hands of a financing corporation and the creditors removed unpaid-for equipment and supplies. Many of the students are reported to have paid full tuition for one year in advance, and so the Attorney General has a problem in attempting to secure some share of justice for the students who claim they had been promised jobs on completing the course.

The incident is instructive and in the newspapers the term "racket" has been employed as characterizing the conduct of vocational schools, of which some other types are under investigation. In passing, it may be noted that "rackets" in medical education have been heard of before today. There is involved here a very comprehensive and complicated problem which goes beyond the question of schools for laboratory workers or milliners, and includes other types of education. Why not all types? The essence of the problem can be stated briefly: the student should receive a fair and just return for his money and his effort.

The offhand answer which finds many supporters is that no educational institution, even if merely vocational, should be established except with the approval of the government. But the requiring of unqualified governmental approval is so incompatible with the freedom of thought and speech which we in this country regard as fundamental to just action, that the other extreme view, favoring no governmental approval, finds extensive support. There is a middle ground which is reasonable. It is that the owners or promoters of the educational institution should show in some concrete way their capacity to meet the financial responsibilities which the conduct of the institution requires. It is possible to obtain in Massachusetts a charter for a medical school, if no degree-conferring power is sought, without any evidence of its owning any property, and even the charter of a degree-conferring university, without evidence that the university possesses any endowment, that is, income-producing property of any sort.

The flagrant abuse in the case noted in the press may be remedied by some patchwork scheme, but what is needed is a new policy on the part of the State to prevent abuses in the future.

The conduct of schools for technicians for clinical laboratories and the conduct of such laboratories without the supervision by qualified physicians present other problems which the medical profession must sometime face.

## POSTPARTUM HEMORRHAGE

Mrs. H. M., a twenty-six-year-old primipara, thirty weeks pregnant, entered the hospital about midnight September 11, 1938, with ruptured membranes but not in labor.

The family and past histories were noncontributory. She had had no serious illnesses and no operations. Catamenia began at thirteen, were regular with a twenty-eight-day cycle and lasted five days without pain. Her last period was February 12, making her due for confinement November 19.

The patient was first seen on June 10. Physical examination showed a well-developed and nourished woman. The lungs were clear. The heart was not enlarged, the sounds regular and of good quality, there were no murmurs. The blood pressure was 114 systolic, 70 diastolic. The fundus was just above the umbilicus, and the fetal heart could not be made out. Vaginal examination showed the cervix soft and closed. On September 2 an x-ray examination confirmed the diagnosis of twins. One vertex was seen in the pelvis, and the other in the left upper quadrant. On September 10, the day before entry, her blood pressure was 115 systolic, 78 diastolic. The fundus was two fingerbreadths below the xiphoid, and a fetal heart was heard. One vertex was below the pelvic brim. Vaginal examination showed the cervix soft but fairly long. There was no internal os.

Labor began about 7 p.m., September 12, its progress was very slow. At 10:30 a.m., September 13, vaginal examination showed that the cervix was dilated so as to admit four fingers, with the first head below the spines of the ischia. The cervix was gently dilated manually, and labor allowed to continue. By 12:30 p.m. she was fully dilated except for the anterior lip. The position was ORA, a forceps was applied, and the first twin was easily lifted over the perineum after a median episiotomy. This child was a boy weighing 3 pounds, 6 ounces. The second sac was then felt intact above the pelvic brim, with the vertex presenting. The sac was ruptured, both feet were grasped, and the child was extracted by the breech after internal

podalic version. A forceps was applied to the after-coming head. This child, also a boy, weighed 3 pounds, 13 ounces. The episiotomy was repaired in routine fashion. The placenta or placentas did not separate. As there was little or no bleeding and the patient seemed in good condition, it was decided to wait. However, at the end of an hour and a half a slight amount of bleeding indicated partial separation. The patient's pulse rate began to rise. Two hours and a quarter after delivery, bleeding became more profuse and the pulse rate jumped to 160. Still no placenta could be expressed, even after 0.25 cc of pituitary extract had been given intravenously. There was obviously no point in waiting longer. The patient and husband were grouped for possible transfusion and were found to be compatible. Under nitrous oxide, oxygen and ether anesthesia, the vagina and uterus were explored. Part of a placenta was detached and protruded through the cervix, but at least two thirds of the two placentas were still adherent over the anterior wall and fundus. The latter portion separated readily when a hand was introduced between the placentas and the uterus, and the two fused placentas, complete with membranes, were extracted. The uterus shut down well, there was no further bleeding. Five per cent glucose solution was given intravenously. The patient's pulse came down to 120, and her condition seemed good. The total loss of blood was estimated at about 500 cc., and there seemed to be no indication for immediate transfusion.

On September 14, the hemoglobin was 56 per cent (Sahli), the red-cell count 3,440,000, and the white-cell count 36,600. She ran a febrile course for about a week and showed a marked anemia. Cultures from both lochia and blood showed no streptococci. On September 20, the hemoglobin was 53 per cent, and the red-cell count 2,600,000. Because of this finding she was transfused with 500 cc of her husband's blood on September 21. Following the transfusion, the patient's temperature rapidly came down to normal, and on September 23 the hemoglobin was 78 per cent, and the red-cell count 3,800,000. She was discharged on the seventeenth day after delivery.

*Comment.* This hemorrhage was due to an adherent placenta which had become partially separated. Its occurrence in a case of twins was purely accidental.

When there is little or no bleeding, it is always safe to wait quite some time after the birth of the baby for the placenta to separate. In this case there was practically no bleeding for over an hour, and then hemorrhage began and continued so that the pulse rate rose to 160. This meant that the

\*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

placenta had partially separated and ruled out further delay in entering the uterus. The entering of a uterus after delivery must be accompanied by perfect asepsis. Infection too often occurs even after the most careful aseptic precautions, particularly following an adherent placenta. In such a case, the uterine sinuses are intimately traumatized and infection is liable to occur. That these fused placentas could be obtained in toto means that the adherence was slight.

Transfusion at the time was not essential. A donor was at hand, but the uterus behaved well and the pulse rate came down immediately. The subsequent transfusion because of the anemia accompanying the sepsis was probably a helpful procedure, but such transfusions must be done only after the most careful checkup. Transfusion is a very valuable method of therapy, but can result disastrously, if the proper precautions are not taken. For such an accident to occur following a transfusion that is not given for the immediate loss of blood is unpardonable.

#### LEGISLATIVE NOTES

Below is listed the progress in the Legislature of some of the bills in which the Massachusetts Medical Society is interested.

##### FAVOR

*S 258* Bill relative to the meaning of the terms rendering medical service, practice of medicine and holding oneself out as a practitioner of medicine and to exempt dentists, optometrists and chiropodists in certain cases from penalties provided for the unlawful practice of medicine. The bill was proposed by the Board of Registration in Medicine. It is favored by the Society with the addition of the following sentence at the end of Section 5A: Such treatment shall include examination of any secretion, excretion or discharge of the living body.

This bill was heard before the Committee on Public Health on February 9, but no report has yet been made.

*H 59* Identical with *S 258*.

This bill was heard at the same time as *S 258* but no report has yet been made.

*H 60* Bill requiring annual licensing of qualified physicians. This bill was proposed by the Board of Registration in Medicine, and gives the necessary powers to the Board. The Council of the Massachusetts Medical Society voted to favor it by a vote of 114 to 34.

It was heard by the Committee on Public Health on February 9, but no report has yet been made.

*H 61* Bill relative to the qualification for membership on the Board of Registration in Medicine. This bill allows any number of members to be members of one medical society.

The bill has been passed to be engrossed.

*H 72* Bill providing for the care of certain infants prematurely born. It was proposed by the Department of Public Health, and corrects defects in the previous bill.

It has been passed by the House and referred back to the

Committee on Ways and Means, where it was heard February 21.

*H 73* Bill providing for supplementary reporting of congenital deformities and birth injuries in infants. The bill was proposed by the Department of Public Health and requires that supplementary reports be sent to this department.

This bill was heard before the Committee on Public Health on January 26 but no report has yet been made.

*H 74* Bill requiring the clerk or registrar in each city or town to give to persons who file notice of intention of marriage suitable information concerning gonorrhea and syphilis. The bill was proposed by the Department of Public Health and it contains no compulsion.

This bill will be heard by the Committee on Public Health, but no date has yet been assigned.

*H 75* Bill making various changes in the laws relating to foods and drugs. The bill was proposed by the Department of Public Health in order to bring the state law into line with the new federal act.

It will be heard by the Committee on Public Health, but no date has yet been assigned.

*H 670* Bill providing for the issuance of certificates of approval of bacteriological laboratories by the Department of Public Health. The bill was proposed by the Massachusetts Public Health Association and is similar to the one favored by the Massachusetts Medical Society last year.

No hearing date has been set by the Committee on Public Health, before which it will be heard.

*H 852* Bill requiring licensing of hospitals, convalescent homes and nursing homes. This bill was proposed by the Massachusetts Central Health Council and provides for the Department of Public Health to set up certain standards of health and enforce them.

It was heard by the Committee on Public Health on February 2, but no report has yet been made.

*H 1407* Bill prohibiting aliens from practicing medicine. This bill was proposed by Rep. Vaughan and is poorly written. It provides that no license be granted to an alien until his first papers have been filed, but allows certain very broad exceptions.

This bill will eventually be heard by the Committee on Public Health.

##### OPPOSE

*H 287* Bill providing for a marriage protection law by requiring a physician's examination and certificate before issuance of marriage licenses. This bill was proposed by Rep. Cutler and it needs major revision before being satisfactory.

It will be heard before the Committee on Public Health at some future date.

*H 551* Bill requiring that notices of intention of marriage shall be accompanied by a physician's certificate that neither party is infected with syphilis. This bill was proposed by Dr. William Frankman and also needs major revision before being satisfactory.

It has been assigned to the Committee on Public Health, and no date has been set for a hearing.

*H 758* Bill providing authority to the Board of Registration of Nurses to limit further training of nurses of all classes and attendants under certain conditions. The bill was proposed by Miss Josephine E. Thurlow, but is against public policy.

It was heard by the Committee on Public Health on February 2, and will be heard again on March 7

*H 759* Bill providing for training and licensing of first-class bedside nurses This bill was proposed by Miss Josephine E Thurlow, but is against public policy

It was heard by the Committee on Public Health on February 2, and will be heard again on March 7

*H 858* Bill regulating the practice of nursing This bill was proposed by the Massachusetts State Nurses Association, and while it is better than last year's bill, some of last year's defects are still present

It was heard by the Committee on Public Health on February 2, but no report has yet been made

*H 985* Bill requiring doctors of medicine and doctors of osteopathy on the Board of Registration in Medicine This bill was proposed by the Massachusetts Osteopathic Association and would put two osteopathic physicians on the Board

It was heard before the Committee on Public Health on February 9, but no report has yet been made

*H 986* Bill providing for a doctor of medicine and a doctor of osteopathy on the Approving Authority and the status of approvals by the American Medical Association and the American Osteopathic Association This bill was proposed by the American Osteopathic Association, it weakens the Approving Authority

This bill was heard February 9 by the Committee on Public Health, but it has not yet made a report

*H 1401* Bill providing that certificates of vaccination or non-vaccination shall no longer be required as a prerequisite to the attendance of any child in public schools This is a typical anti vaccination bill

It will be heard before the Committee on Public Health but no date has yet been assigned for the hearing

*H 1998* Bill providing for the establishment and administration of a system of health insurance This bill was proposed by the State Industrial Council of the Congress of Industrial Organization (CIO) and means complete state insurance with a 4½ per cent payroll tax It represents real regimentation of physicians

It will eventually be heard by the Committee on State Administration

## MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning February 27

### BARNSTABLE

Sunday, March 5, at 4 00 p m., at the Cape Cod Hospital, Hyannis Subject—Bleeding in the Third Trimester of Pregnancy Instructor Meinolf V Kappius Donald E Higgins, *Chairman*

### BRISTOL NORTH

Thursday, March 2, at 4 00 p m., at the Morton Hospital, Taunton Subject—Operative Obstetrics Instructor Roy J Heffernan Lester E Butler, *Chairman*

### BRISTOL SOUTH (Fall River Section)

Tuesday, February 28, at 4 00 p m., at the Union Hospital, Fall River Subject—Whooping Cough The present status of vaccine therapy both as pro-

phylactic and therapeutic measure, the early diagnosis by laboratory procedures, and the treatment of complications Instructor R Cannon Eley Howard P Sawyer, *Chairman*

### HAMPDEN

Thursday, March 2, at 4 00 p m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8 00 p m., in the Outpatient Department of the Skinner Clinic, Holyoke Hospital, Holyoke Subject—Anemia Modern methods in diagnosis and treatment of blood dyscrasias Instructor Chester S Keefer George L Schadt, *Chairman*

### MIDDLESEX EAST

Tuesday, February 28, at 4 00 p m., at the Melrose Hospital (Colby Hall), Melrose Subject—Bright's Disease and Hypertension Evaluation of new therapy, diagnosis Instructor Laurence B Ellis Walter H Flanders, *Chairman*

### MIDDLESEX NORTH

Thursday, March 2, at 4 30 p m., at St. John's Hospital, Lowell Subject—Heart Disease The treatment of "heart attacks" or "cardiovascular emergencies" Instructor Howard B Sprague William S Lawler, *Chairman*

## DEATHS

**COREY**—FREDERICK H COREY, M.D., of 439 Union Street, Rockland, died February 18 He was in his sixty second year

Born in Charlestown he received his degree in 1904 from Tufts College Medical School Dr Corey was a fellow of the American Medical Association and of the Massachusetts Medical Society

**HARTNETT**—EDWARD D HARTNETT, M.D., of 62 Prescott Street, East Boston, died February 14 He was in his sixty-sixth year

Born in East Boston he received his degree from the Harvard Medical School in 1898 and entered practice the same year Dr Hartnett was a member of the Massachusetts Medical Society and the American Medical Association

Dr Hartnett was unmarried and a brother and two sisters survive him

## MISCELLANY

### MEDICAL MOTION PICTURES AVAILABLE FOR LOAN

Motion pictures on various scientific subjects of medical interest are available on a loan basis from the American Medical Association

Requests for films should be instituted as far in advance as possible, so that the proper reservations can be made The exact shipping addresses and dates should be given at the time of the request, also the type of apparatus in which the film is to be run Responsibility for the projection and care of the film must be borne by the individual or organization which is borrowing it The American Medical Association does not have projectors available for loan

The only expense usually incurred is that of transportation both ways However, careless handling resulting in serious damage may be charged to the borrower

A brief description of each film is given in the following list. Inquiries should be addressed to Dr. Thomas G. Hull, 535 North Dearborn Street, Chicago, Illinois

*Syphilis A motion picture clinic* Sound. 35 mm and 16 mm. Running time, about 1½ hours

The diagnosis and treatment of syphilis presented by national authorities.

*Cancer (Canti cancer film)* Silent. 35 mm Running time, about 45 minutes

A film demonstrating the proliferation of cell tissue and the formation of cancers.

*Blood Circulation (Harvey blood film)* Silent. 35 mm Running time, about 45 minutes.

An attempt has been made to reproduce the dissections and experiments performed and described by Harvey himself, and here explained in the main by extracts from Robert Willis's translation of Harvey's book.

*Blood Transfusion* Silent. 16 mm. Running time, about 45 minutes.

Three methods of blood transfusion, illustrated in detail

*Comparative Physiology of Labor* Silent. 16 mm Running time, about 1 hour

Demonstration of normal labor in the human being, the horse, the cow, the sheep, the dog, the pig and rabbit.

*Effects of Heat and Cold on the Circulation of the Blood* Silent. 16 mm. Running time, 12 minutes

Demonstration of the effect of heat and cold on circulation, as seen through a glass chamber installed in a rabbit's ear

*Effects of Massage on Circulation of Blood* Silent. 16 mm. Running time, 8 minutes.

Demonstration of the effect of massage on circulation, as seen through a glass chamber installed in a rabbit's ear

*Contraction of Arteries and Arteriovenous Anastomoses* Silent. 16 mm. Running time, 10 minutes.

This film visualizes the contraction of arteries and arteriovenous anastomoses as seen through a glass chamber installed in a rabbit's ear

*Therapeutic Exercises for the Shoulder Joint Following Dislocation* Silent. 16 mm. Running time, 10 minutes

Demonstration of static, passive, active and resistive exercises for the shoulder joint, using simple apparatus.

*Treatment of Compression Fracture of the First Lumbar Vertebra* Silent. 16 mm. Running time, about 12 minutes

This film shows physical therapy procedures to be administered to a fracture of the first lumbar vertebra during a patient's confinement in bed and immediately following

*Aids in Muscle Training* Silent. 16 mm Running time, about 12 minutes.

Demonstration of sling suspension exercises for the upper and lower extremities, graded exercises on a powdered board for the lower extremities, and three kinds of walkers for re-education exercises

*Underwater Therapy* Silent. 16 mm Running time, about 16 minutes

Presentation of the therapeutic use of large and small exercise pools, Hubbard tanks and homemade tanks, and demonstration of types of exercises given in cases such as those with infantile paralysis and cerebral palsy and following operation for congenital dislocation of the hip

*Occupational Therapy* Silent. 16 mm. Running time, 12 minutes.

This film demonstrates occupations that may be prescribed by physicians to motivate and control the desired physical or mental activity of the patient and assist in his adjustment to long hospitalization. A section on cerebral palsy is included, picturing indirect muscle training through prescribed activity and stressing the importance of early treatment to prevent growth of faulty habit patterns.

*Massage* Silent. 16 mm. Running time, 4 minutes.

Demonstration of the technic of massage, describing the various movements and showing why they are performed in a given way

#### ART TELLS HISTORY OF AMERICAN MEDICINE

Beaumont and St. Martin is the first of six large paintings in oil memorializing Pioneers of American Medicine which artist Dean Cornwell will complete in the next few years. Others in the series are Oliver Wendell Holmes, Ephraim McDowell, Crawford W. Long, William T. G. Morton, Major Walter Reed and one

'Beaumont and St. Martin'

woman, Dorothea Lynde Dix, who, while not a physician, stimulated physicians to study insanity and feeble-mindedness

Arrangements to supply physicians with free, full-color reproductions of 'Beaumont and St. Martin', without advertising and suitable for framing, have been made with the owners, John Wyeth & Brother, 1118 Washington Street, Philadelphia.

#### NOTE

The following appointments to the teaching staff at the Harvard Medical School were recently announced

Francis F. Hart, of Ambler, Pennsylvania, as resident physician to the Collis P. Huntington Memorial Hospital and research fellow in medicine, M.D. University of

Pennsylvania '36, John Pifers, of Detroit, Michigan, as assistant in pediatrics, M D University of Toronto '34

The annual Theobald Smith Memorial Lecture of the New York Society of Tropical Medicine was given on January 20 at Cornell University Medical College, New York City, by Dr Richard P Strong, professor of tropical medicine emeritus, Harvard Medical School His topic was 'Malarial Diseases in the Western Hemisphere.'

will benefit by conservative treatment until a comparatively safe cholecystectomy can be performed

D C PATTERSON, M.D

881 Lafayette Street,  
Bridgeport, Connecticut.

## BOSTON DOCTORS SYMPHONY ORCHESTRA

It is gratifying to announce that a doctors symphony orchestra is being formed under the direction of a famous international conductor, Nicolas Slonimsky It will not only be a musical treat but a privilege to play under a man who is also well known as a composer, critic, essayist and authority on modern music and musicians

Music as a hobby is so widespread among doctors—the New York Doctors' Symphony Orchestra has over a hundred members—that an organization of this sort should be a source of pleasure as well as a pride to professional groups

All physicians, dentists and medical and dental students who are interested in joining should communicate with Dr Julius Loman, Pelham Hall Hotel, Brookline (BEA 2430) Meetings will be held at Hampton Court Hotel, 1223 Beacon Street, Brookline, every Thursday evening at 7 30, starting March 9

H. L. CABITT, MD,  
JULIUS LOMAN, M.D.,  
H. W. PARKER, M.D

## CORRESPONDENCE

### OPERATIONS FOR ACUTE GALL-BLADDER DISEASE

*To the Editor* There have been not a few papers written, and considerable discussion, in the past few years regarding the respective advantages of immediate and delayed operations in acute gall bladder disease The use of this term immediate by some authorities has, I think, been confusing and does not express their real intent It is to be noted that the authorities advising an immediate operation also state that the patient should have proper preoperative preparation and that twenty four to forty-eight hours can be well spent in such a preparation This takes the operation out of the immediate class, for most of us understand immediate operation to mean an operation as soon as possible, for example in a true emergency or in the usual case of acute appendicitis

A very small number of cases of gall bladder disease can be classed as emergencies requiring immediate operation Cases of perforation of the gall bladder and fulminating cases of empyema certainly come under such a classification, but to urge immediate operation for acute cholecystitis in general will lead to much harm Teachers of surgery who lend prestige and support to a policy of immediate operation in all cases provide authority for rash surgeons, inexperienced operators and uninformed practitioners

To liken acute cholecystitis to acute appendicitis is not reasonable, for it is but seldom that the two conditions progress in a similar manner There is no question about the benefits of surgery in acute appendicitis, but there are many well informed men who believe that the persistence of symptoms in such a large percentage of patients who have been operated on for cholecystitis brings up a justifiable doubt as to its value In view of this fact, and when it is further shown by a carefully studied series that 37 per cent of the cases of acute cholecystitis subside without intervention, the foundation for advising immediate operation in all cases is not any too firm furthermore, most surgeons favor cholecystectomy over cholecystostomy, and the former by a standard technic or any of the various modifications is out of the question in many of these cases

There is a possibility that some men misled by the use of the term immediate by teachers of surgery may feel justified in rushing in on cases of acute cholecystitis that would be much better off if the patient were treated otherwise for a day or two There might also be a change in diagnosis in some cases, by the light of another day The term "early" operation would be more applicable to the procedure in discussion and would no doubt receive the approval of many surgeons who are not willing to subscribe to the dictum of immediate.

Cases of acute cholecystitis should be studied individually Some will require immediate operation, some will be better for a few hours' or days preparation, and some

## REPORTS OF MEETINGS

### HARVARD MEDICAL SOCIETY

A meeting of the Harvard Medical Society was held on November 8, 1938

Dr Charles Stone presented the medical case. A thirty four year-old, single American factory worker was admitted with a story of seven or eight convulsive attacks in the last nine years, without aura, cry, biting of the tongue or loss of sphincter control Five years previous to admission there was a snap in the back of the head, blurred vision, diplopia, nausea, vomiting and inability to move the head, coming on suddenly Lumbar puncture showed grossly bloody fluid She improved after two months in bed, during which time she suffered from dizzy headaches, vomiting, impairment of memory, retention of urine and constipation Since that time there had been frequent headaches, some relieved only by lumbar puncture Two months previously she had had another similar attack, relieved by rest She had had frequent nosebleeds in her childhood Physical examination revealed a well-developed girl, with fundal arteries slightly increased in tortuosity No angiomas were seen in the fundi or in the nasal mucosa The lungs were clear There was a blowing systolic murmur at the apex of the heart The abdomen was negative, and the reflexes physiological The blood pressure was 140 systolic, 100 diastolic, and subsequently fell to 128 systolic, 78 diastolic The visual fields and caloric tests were normal The urine and stool examinations were normal The blood showed a red-cell count of 4,680,000 with 96 per cent hemoglobin, and a white-cell count of 8200 with 50 per cent polymorphonuclears The smear was normal The blood Wassermann and Hinton tests were negative Spinal fluid examination showed a clear colorless fluid with an initial pressure of 180 mm of water, the Pandy and ammonium sulfate tests were negative there were 15 red blood cells per cubic millimeter, undoubt

edly traumatic. The total protein was 30 mg per cent, and the gold sol curve flat. The spinal fluid Wassermann test was negative. Electroencephalograms, done subsequent to discharge, were reported as showing multiple foci of cortical disorder, worse in the temporal motor and occipital leads, worse on right than on left and most clearly abnormal in right temporal area. The absence of a single, clear, constant focus was said to be against brain tumor, abscess or fresh hemorrhage. Diagnosis spontaneous subarachnoid hemorrhage (? congenital aneurysm, ? angiomas, ? hypertension)

Dr James B Campbell presented the surgical case. A fifty-three-year-old woman had suffered from frequent headaches for the past twenty years. Five months before entry she experienced an attack of vertigo, nausea and emesis, and fell to the left. Since this attack she had been unsteady on her feet. Five days before entry she experienced a recurrent attack similar to the one previously noted, and had had headaches in the right frontal region since that time. *There was staggering gait, with a tendency to fall to the left, astereognosis, adiodochokinesis, nystagmus, choked disks bilaterally, and a slightly stiff neck. The visual fields were grossly normal. The blood pressure was 196 systolic, 140 diastolic. Electroencephalography was performed. Ventriculography showed a clear fluid with a low protein content (2 mg per cent) and a few red blood cells. There was dilatation of the lateral ventricles, and the third ventricle was seen to be widened in the posteroanterior skull plate.*

Dr Hallowell Davis discussed the electroencephalographic tests which he had performed on the patient. There was considerable abnormality of the brain waves in practically all portions of the cerebrum, a finding consistent with generalized increase in intracranial pressure. If there is generalized increase in pressure there is little chance of localizing brain lesions by electroencephalography. Dr Ayer stated that between 30 and 40 per cent of cases with brain tumors show no increase in intracranial pressure. In these cases electroencephalography should be of great aid in localization of the lesion. In cases in which the pressure is increased, air encephalography is necessary. Dr James Poppen remarked that the signs, symptoms and x-ray evidence in this case pointed to a lesion in the cerebellum.

Dr Tracy J Putnam talked on 'Recent Developments in the Treatment of Neurological Diseases: Epilepsy, hydrocephalus, athetosis and paralysis agitans'. He first discussed epilepsy, pointing out the tremendous cost in money and human suffering caused by the 500,000 cases of epilepsy existent in the United States. The number of persons suffering from this disease is approximately equal to the number of cases of tuberculosis or of diabetes in the United States. Perhaps the greatest advance in the treatment of epilepsy until recent days was made in 1912 when the use of phenobarbital to control the disease was introduced. Attempts to resect the cortex and prevent seizures by other surgical measures have not been very successful, and medical therapy is still the most useful means of control.

He mentioned how he and Dr Houston Merritt had attempted to develop a compound which would be more successful than phenobarbital in controlling epilepsy. They found that abnormalities in the electroencephalograms of cats could be produced by passing electric currents through their craniums, and that these abnormalities were very similar to those observed in human encephalograms taken during attacks of epilepsy. They then found that convulsive seizures and typical electroencephalograms were produced in individual animals by a fairly constant amount of current. The threshold at which seizures were pro-

duced was constant enough to be used as a standard to test the effect of various substances in preventing or decreasing convulsions. Different drugs were administered to these animals in an attempt to raise the threshold at which seizures occurred. Phenobarbital was the only member of the barbiturate group which produced the desired effect. They therefore believed that the phenyl group was responsible for the depressant effect rather than the barbiturate group. One hundred phenyl derivatives were selected for trial, and of these diphenyl hydantoin was found to be the most satisfactory. This drug was then administered to patients with epilepsy with the result that 60 per cent were relieved of their symptoms. Work is still being carried on in an attempt to find an even more potent compound.

The attempts at treatment of internal hydrocephalus by surgical means were next described. Dr Putnam developed the bipolar glass ventriculoscope which enables him to cauterize the choroid plexus without causing injury to the basal ganglia. *Following the last ten such operations there has been only one death. There are two types of infants with internal hydrocephalus. The first and commonest type is found in patients with multiple developmental defects, who are usually imbeciles. Operative therapy in such cases is hopeless and is contraindicated. The minority of cases show no abnormality other than an increased intraventricular pressure, and in these, operative therapy can be expected to bring relief. Dr Putnam has several such cases which have survived four years after the operation and are developing normally.*

Athetosis is a disease following birth injury in which the muscles of one or more extremities or the neck are the seat of constant involuntary movements. These involuntary movements are caused by an irregular innervation of all the muscle groups of the extremity simultaneously. It was believed that the impulses causing these movements traveled down the extrapyramidal tracts, and several cases were subjected to section of the anterolateral tracts with marked improvement of symptoms.

Paralysis agitans is an alternating tremor caused by the alternate discharge of nerve impulses from cells supplying the flexor and extensor groups of muscles at a slow rate of five to eight impulses per second. Very little energy is expended by such tremors. In the belief that the impulses causing such tremors were carried down the extrapyramidal tracts, as was the case in athetosis, section of these tracts was performed. There was no change in the tremor. It was then suspected that the impulses were mediated by the pyramidal tracts, and these tracts were sectioned in two cases with return of function. There was subsequent recurrence of tremor in one of the cases, and a second operation was performed with a wider incision in the spinal cord. Following this operation there was abolition of the tremor and a partial restoration of function. Motion pictures were shown which demonstrated the great relief and the restoration of partial function in these cases.

## NOTICES

### FAULKNER HOSPITAL CLINICOPATHOLOGICAL CONFERENCE

The monthly clinicopathological conference of the Faulkner Hospital will be held on Thursday, March 2, at 5 00 p m.

There will be a discussion of cases by Dr James M Faulkner and Dr John W Spellman

# BOSTON DOCTORS SYMPHONY ORCHESTRA

*Nicolas Slonimsky*

The newly organized Boston Doctors Symphony Orchestra, conducted by Nicolas Slonimsky, will start rehearsing on March 9. Rehearsals will be held every Thursday evening at 7:30 at Hampton Court Hotel, 1223 Beacon Street, Brookline.

Membership is still open. All physicians, dentists and medical and dental students who are interested should communicate with Dr. Julius Loman, Pelham Hall Hotel, Brookline (BEA 2430).

### MEDICAL CONFERENCE PROGRAM

- Wednesday, March 1—Hospital Case Presentation. Dr. S. J. Thannhauser.  
 Thursday, March 2—Some Aspects of the Social Setting of Medical Practice. Dr. Talcott Parsons.  
 Friday, March 3—Title to be announced. Dr. E. D. Churchill.  
 Saturday, March 4—Hospital Case Presentation. Dr. S. J. Thannhauser.  
 Tuesday, March 7—Diagnosis and Treatment of Certain Bone Tumors. Dr. J. D. Adams.  
 Wednesday, March 8—Hospital Case Presentation. Dr. S. J. Thannhauser.  
 Thursday, March 9—Laboratory Aids in the Detection of Gonococcus Infection. Dr. W. A. Hinton.  
 Friday, March 10—Functional Disturbances of the Gastrointestinal Tract. Dr. J. H. Means.  
 Saturday, March 11—Hospital Case Presentation. Dr. S. J. Thannhauser.  
 Tuesday, March 14—Compression of Cancellous Bone, Manifestations in the head and neck of the femur, treatment by drill channels. Dr. Eugene Bozsán.  
 Wednesday, March 15—Hospital Case Presentation. Dr. S. J. Thannhauser.  
 Thursday, March 16—Syphilitic Optic Atrophy (with lantern slides). Dr. S. H. Epstein.  
 Friday, March 17—Treatment of Diseases of the Pericardium. Dr. C. S. Burwell.  
 Saturday, March 18—Hospital Case Presentation. Dr. S. J. Thannhauser.

- Tuesday, March 21—Clinicopathological Conference. Dr. Harold Wood.  
 Wednesday, March 22—Hospital Case Presentation. Dr. S. J. Thannhauser.  
 Thursday, March 23—Certain Aspects of the Toxemias of Pregnancy. Dr. Lewis Dexter.  
 Friday, March 24—Title to be announced. Dr. H. H. Merritt.  
 Saturday, March 25—Hospital Case Presentation. Dr. S. J. Thannhauser.  
 Tuesday, March 28—X-ray Demonstration. Dr. Alice Ettinger.  
 Wednesday, March 29—Hospital Case Presentation. Dr. S. J. Thannhauser.  
 Thursday, March 30—Recent Concepts in the Etiology of Migraine. Dr. Arnold Zetlin.  
 Friday, March 31—Clinical Studies and Biochemistry of Virulism. Dr. H. B. Friedgood.

## TUFTS MEDICAL ALUMNI LECTURE

The annual alumni lecture will be given at Tufts College Medical School on Thursday, March 2, at 4:00 p. m. Dr. Frank Ober, Tufts College Medical School '05, will speak on "In Medicine, Your Invested Capital Is Your Brain. How do you propose to increase your investment?" Physicians and medical students are cordially invited to attend.

## HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held on Tuesday, February 28, in the Peter Bent Brigham Hospital amphitheater (Shattuck Street entrance), at 8:15 p. m.

### PROGRAM

Presentation of cases.  
 Further Experiences with Cyanate Therapy in Hypertension. Dr. Roger W. Robinson and Dr. James P. O'Hare.

Medical students and physicians are cordially invited to attend.

ROBERT ZOLLINGER, M.D., *Secretary*

## WORCESTER DISTRICT MEDICAL SOCIETY

The next meeting of the Worcester District Medical Society will be held at the Worcester Memorial Hospital, on Wednesday, March 8.

### PROGRAM

Micro-anatomic Changes in Shock. Dr. James S. Beck.  
 Peripheral Vascular Disease. Dr. George R. Dunlop.  
 Experiences with the Thiocyanate Treatment of Hypertension. Dr. Roger W. Robinson.

GEORGE C. TULLY, M.D., *Secretary*

## MEDICAL CLINIC AT THE PETER BENT BRIGHAM HOSPITAL

At 3:30 p. m. on Thursday, March 2, in the amphitheater of the Peter Bent Brigham Hospital, Dr. Henry A. Christian, Hersey Professor of the Theory and Practice of Physic, Harvard Medical School and physician-in-chief, Peter Bent Brigham Hospital, will give a medical clinic. Practitioners and medical students are cordially invited to attend.

## BOSTON HEALTH LEAGUE

The annual meeting of the Boston Health League will be held on Thursday evening, March 2, at The Sheraton, Bay State Road, Boston, at 6 30. The program includes dinner, a short business meeting and a guest speaker. Mr. George St. J. Perrott, secretary of the Interdepartmental Committee to Co-ordinate Health and Welfare activities, of Washington, District of Columbia, will speak on 'Community Services and the National Health Program.'

Reservations for dinner, \$1.50 a plate, should be made at the office of the Boston Health League, 80 Federal Street, before February 28 (LIB 8515). Physicians unable to attend the dinner are invited to come and hear Mr. Perrott at 8 00.

## QUINCY CITY HOSPITAL

A series of Sunday afternoon health lectures will be given under the auspices of the Quincy City Hospital in the administration building at 3 00 p. m., beginning March 5 and ending May 7, 'Hospital Sunday'. These lectures will be given in preparation for the observance of National Hospital Day, Friday, May 12. Admission will be free and restricted to adults. The schedule is as follows:

March 5 Broken Bones How they should be handled and treated.

Stomachaches Appendicitis and gall-bladder disease.

March 12 Diabetes Its causes and latest treatment.  
Good Mental Hygiene in the Home.

March 19 Cancer—Tumors Causes and treatment.

March 26 Food—Weight—Health

April 2. What Not to Feed Your Baby  
Moving Picture—'Child Hygiene.'

April 9 Prenatal and Postpartum Care of the Mother and Child.

April 16 The Prevention and Care of Infections.  
Nursing Procedures

April 23 Pneumonia Its causes and treatment.  
Sound Moving Picture—'Pneumonia.'

April 30 Common Skin Diseases and Their Treatment.  
Sound Moving Picture—'Tuberculosis.'

May 7 Nursing Procedures in a Modern Hospital.  
Hospital Insurance and Social Security

## EDWARD K. DUNHAM LECTURES

The Faculty of Medicine of Harvard University has announced that the following lectures will be given by Dr. K. Linderstrom Lang, director of the Chemical Department, Carlsberg Laboratory, Copenhagen, under the Edward K. Dunham Lectureship for the Promotion of the Medical Sciences:

Monday, March 6 Micromethods for the Determination of Enzymes.

Wednesday, March 8 Distribution of Enzymes in Cells and Tissues

Friday, March 10 Proteins and Proteolytic Enzymes

These lectures are scheduled for 5 00 p. m. at the Harvard Medical School, Amphitheater, Building C.

UNITED STATES CIVIL SERVICE  
EXAMINATION

Physiotherapy Aide, \$1,800 a Year  
Physiotherapy Pupil Aide, \$1,440 a Year

Applications must be on file with the United States Civil Service Commission at Washington, District of Columbia, not later than March 13.

Applicants for the physiotherapy aide must have been graduated from a school of physiotherapy meeting the standards established by the American Medical Association, or must have had at least eighteen months of experience as a classified pupil aide in physiotherapy in a Veterans' Administration Facility.

Applicants for the physiotherapy pupil aide must have successfully completed a full four-year high-school course or they must have successfully completed at least fourteen units of high school study acceptable for college entrance.

## SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING  
MONDAY, FEBRUARY 27

## MONDAY FEBRUARY 27

\*8 15 p. m. New England Heart Association Peter Bent Brigham Hospital

## TUESDAY FEBRUARY 28

\*9 10 a. m. Joseph H. Pratt Diagnostic Hospital. Diabetic Clinic. Dr. Joseph Rosenthal

\*10 a. m. 12 30 p. m. Tumor clinic. Boston Dispensary  
5 p. m. Hospital Research Council. Ether Dome of the Massachusetts General Hospital

\*8 15 p. m. Harvard Medical Society Peter Bent Brigham Hospital amphitheater (Shattuck Street entrance)

## WEDNESDAY MARCH 1

\*9 10 a. m. Joseph H. Pratt Diagnostic Hospital. Hospital case presentation. Dr. S. J. Thannhauser

\*12 m. Clinicopathological conference. Children's Hospital amphitheater

## THURSDAY MARCH 2

8 30-9 30 a. m. Exchange visit Surgical and Orthopedic Staffs of the Peter Bent Brigham and Children's hospitals, held this week at the Peter Bent Brigham Hospital

\*9 10 a. m. Joseph H. Pratt Diagnostic Hospital. Some Aspects of the Social Setting of Medical Practice. Dr. Talcott Parsons.

\*3 30 p. m. Medical clinic at the Peter Bent Brigham Hospital

\*4 p. m. Tufts Medical Alumni Lecture.

5 p. m. Faulkner Hospital clinicopathological conference.

\*6 30 p. m. Boston Health League. The Sheraton 91 Bay State Road Boston.

## FRIDAY MARCH 3

9 10 a. m. Joseph H. Pratt Diagnostic Hospital. Title to be announced. Dr. E. D. Churchill

10 a. m. 12 30 p. m. Tumor clinic. Boston Dispensary

12 m. Clinical meeting of the Children's Medical Service. Massachusetts General Hospital. Ether Dome.

12 m. Urological conference, Massachusetts General Hospital lower outpatient amphitheater

## SATURDAY MARCH 4

\*9 10 a. m. Joseph H. Pratt Diagnostic Hospital. Hospital case presentation. Dr. S. J. Thannhauser

\*10 a. m. 12 m. Staff rounds of the Peter Bent Brigham Hospital Conducted by Dr. Henry A. Christian.

## SUNDAY MARCH 5

4 p. m. Illustrated public health lecture, Faulkner Hospital auditorium. The Surgical Treatment of Female Disorders. Dr. P. Francis Weiss.

4 p. m. Free public lecture, Harvard Medical School Amphitheater of Building D. Vitamin Deficiencies. Dr. S. Burt Wolbach.

Open to the medical profession.

## BOOK REVIEWS

*The Medical Applications of the Short Wave Current*  
William Bierman Including a discussion of its physical and technical aspects by Myron M. Schwarzschild  
379 pp Baltimore William Wood & Co., 1938 \$5.00

The principles of physics underlying short wave currents may hardly lay claim to being common knowledge. Considerable information of this type can be acquired by carefully studying—not merely reading—the first part of this book. Here we find ample clarification of such topics as inductance and capacity and their interrelation. The comparison of radio-tube and spark gap ap-

paratus and the discussion of frequencies and wave lengths will interest many a reader, since many manufacturers and dealers lay stress on these aspects of short wave machines.

This is followed by a section on temperature determinations, which are the backbone of short wave diathermy; whatever else may be said about these currents all agree that they are thermogenetic. Hence one welcomes the recorded observations of temperature changes in the human thigh produced by 6-, 12-, 18- and 24 meter wave lengths. These measurements were taken at skin surface, subcutaneously and in intramuscular areas as close as 0.3 cm. to the periosteum of the femur. There are also tables of temperature changes produced in the paranasal sinuses and in the female pelvis. The conclusion is drawn that over the range of wave lengths tested there is no appreciable difference in thermal effect, provided the intensity of the treatment is gauged by the sensation of the subject. Nor were there observed any distinct differences between radio-tube and spark gap machines or between coil and cuff techniques in applying the electrode to the thigh.

A lengthy discussion of the physiologic responses to local heat and local short-wave currents follows. This deals with changes in the circulatory, digestive and nervous systems, effects on growth and reproduction, effects on bacterial infections and inflammations, and effects on cells and tumors. This chapter concludes with a consideration of the injurious effects of short wave currents.

While the authors admit that they are dubious of any effect produced by short-wave currents other than that of thermogenesis, they sum up the opinions and findings of those who claim special effects.

In the last section the techniques of application and the treatment of various diseases are taken up. The cuts materially help the descriptions given in the text for the methods commonly and uncommonly used. References are frequently made to theoretical considerations which are presented in the first part of the book.

Drs. Bierman and Schwarzschild are to be congratulated on having made a very valuable contribution to the literature of short-wave currents and short wave therapy.

*Physical Diagnosis* Richard C. Cabot and F. Denette Adams Twelfth edition 846 pp Baltimore William Wood & Co. 1938 \$5.00

Offered as the twelfth edition of a text first published thirty-eight years ago, this volume has little in common with the Cabot we were brought up on, beyond a scattered few of the old diagrams. Abandoning the senior author's original purpose of presenting an account of the diagnostic methods and processes needed by competent practitioners of the present date, the new book aims rather to discuss the physical signs of disease in their relation to symptomatology and clinical entities. Perhaps this currently popular method of teaching physical diagnosis is sound, but one cannot help believing that the second year medical student is hardly ready for it. His first need as he is initiated into the art of the clinic is for a propaedeutic manual. However, the book admirably fulfills its stated purpose, and will serve as a valuable though not exhaustive reference volume for the house officer and practitioner.

There are a few proofreader's errors, such as "Sprengel" for "Sprengel" (p. 180), "palpation" (p. 235), "Ludwig's angle for Louis's angle" (p. 244), "portodiastolic" (p. 260), "cirrhosis" (p. 479), "contra coup" (p. 790) and "guaze" (p. 764), but no important deviations from what is generally accepted as sound theory and established fact.

## TREATMENT OF PNEUMOCOCCUS TYPE 3 PNEUMONIA WITH SPECIFIC SERUM AND SULFANILAMIDE\*

MAXWELL FINLAND, M.D.,† AND JOHN W. BROWN, M.D.‡

BOSTON

THE recent introduction of therapeutic anti-pneumococcus rabbit serums and of sulfanilamide and similar compounds have stimulated interest in the possibility of favorably influencing the severe and highly fatal pneumonias associated with the Type 3 pneumococcus. This paper deals primarily with the clinical results obtained at the Boston City Hospital, prior to July, 1938, in the treatment of 56 such cases with specific serum and sulfanilamide, used separately or in combination. In a number of these cases there was an opportunity to make immunological observations, the details of which are being reported elsewhere<sup>1</sup>.

The favorable reports of Heintzelman, Hadley and Mellon<sup>2</sup> and of Sadusk<sup>3</sup> on the treatment of Type 3 pneumonia with sulfanilamide are of interest but are not convincing. Only a small number of cases are included, and there were no patients with bacteremia who recovered. Bullowa<sup>4</sup> is quoted as having used the drug alone to treat 10 cases including 5 with bacteremia. Among his cases there were 2 deaths, both in bacteremic patients. The use of rabbit serum in the treatment of small numbers of cases of pneumococcus Type 3 pneumonia has been reported.<sup>5,6</sup> No convincing drops in death rates have been noted, but the survival of an occasional bacteremic patient is suggestive of beneficial therapeutic effect.

### PATIENTS, MATERIALS AND METHODS

All the patients included in this study had acute pulmonary infection with evidence from physical and x-ray examinations of either lobar or atypical (broncho-) pneumonia. In each case Type 3 pneumococci were obtained either from the blood culture or directly from one or more specimens of sputum by the Neufeld method or after mouse inoculation or both. The therapeutic serums used

were mostly concentrated rabbit serums supplied by the Lederle Laboratories, Incorporated, of Pearl River, New York. Experimental methods were used in the production and concentration of most of these serums. Their potency varied in different lots from 1000 to 5000 provisional units per cubic centimeter, but many lots were not standardized. One lot of unconcentrated rabbit serum was furnished by the Antitoxin and Vaccine Laboratory of the Massachusetts Department of Public Health. All the serums were given in graded doses intravenously with the same general precautions as were used for other horse or rabbit serums. Sulfanilamide was usually given by mouth, but in occasional severely ill patients it was given subcutaneously in 0.8 per cent solution in physiological saline. The usual dose was 8 gm. during the first eight to twenty-four hours then 6 to 8 gm. daily, given in equal divided doses at four hour intervals, together with the same or half the amount of sodium bicarbonate. The dose was decreased or omitted when definite improvement was evident. Dosage was also varied to suit individual circumstances. The supply of serum available during this study was limited. When available its use was usually reserved for the patients who appeared most ill, and then sulfanilamide was also given. In some of the patients, treatment with serum was discontinued either because the supply was exhausted or, with some of the earliest experimental lots, because of severe reactions.

### IMMUNOLOGICAL STUDIES

In vitro studies were carried out to ascertain the effect of sulfanilamide and serum, alone or in combination, on the growth of Type 3 pneumococci in the blood of patients acutely ill with pneumonia due to this organism. The details of these studies and of the tests done in the same patients after treatment are presented elsewhere.<sup>1</sup> It suffices here to summarize the results of these studies and to give our interpretation of the significance of these results in understanding the effect of treatment on the mechanism of recovery in this disease.

It was found that sulfanilamide in concentrations of about 7 mg. or more per cent exerts a bacteriostatic action on large numbers of Type 3 pneumococci in the blood of non-pneumonic individuals or of patients ill with pneumonia due to

this organism, when such bloods alone lack pneumococidal activity. The drug probably does not influence phagocytosis in these bloods. It usually exerts no bactericidal effect in a concentration of 10 mg per cent but may do so occasionally with greater concentrations.

Patients with pneumococcus Type 3 pneumonia whose blood is bactericidal for pneumococci of this type during the acute disease and before treatment usually acquire homologous type-specific agglutinins, mouse-protective antibodies and phagocytic activity after treatment with either sulfanilamide or serum or both. Blood invasion does

either the serum or the sulfanilamide are used separately.

In patients whose blood lacks pneumococidal properties, treatment with sulfanilamide probably renders the blood bacteriostatic until heat stable specific antibodies (agglutinins and mouse protective antibodies) develop or until a balance of such antibodies is passively introduced. When such heat-stable antibodies are acquired, the pneumococcal infection usually subsides. With specific antiserum in proper amounts, the infection may be overcome without the additional use of sulfanilamide, especially in patients who are not

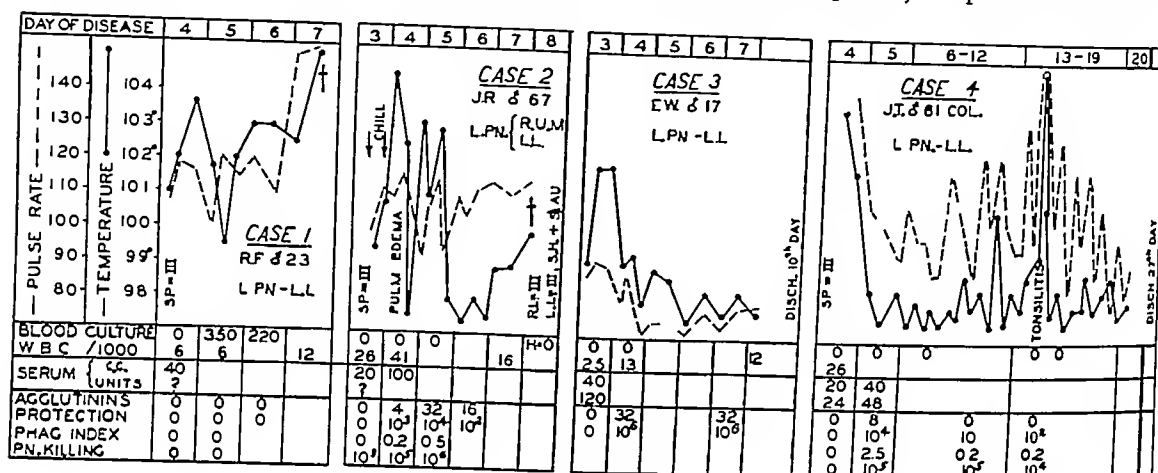

Figure 1 Patients Treated with Specific Serum

not occur after treatment in such cases, and if death occurs, it is usually a result of a superinfection or of other conditions not directly related to the Type 3 infection. In an occasional patient the pulmonary process extends in spite of the presence of circulating antibodies and in the absence of bacteremia.

Therapeutic Type 3 antipneumococcus rabbit serums induce pneumococidal activity in the blood of patients ill with pneumonia due to this type. These antiserums and sulfanilamide used together produce a greater bacteriostatic and bactericidal effect than when equivalent amounts of

heavily infected. Death may occur in either event, but under such circumstances it is due either to complications or to conditions not related to the Type 3 infection.

Occasional patients recover following sulfanilamide therapy without the development of homologous type-specific antibodies. This may occur even when the Type 3 pneumococcus has been recovered from the blood stream.

#### CLINICAL RESULTS

The pertinent data in each of the treated patients in whom special immunological studies

#### EXPLANATION OF FIGURES 1-3

**Blood culture** 0 = no growth + = positive for pneumococcus Type 3  
Numbers represent number of colonies of pneumococcus Type 3 per cubic centimeter of blood

**W B C** White blood corpuscles — in thousands per cubic millimeter

**Serum** Type 3 antipneumococcus rabbit serum. After units, the numbers represent thousands of units. (The unit is defined as ten times the smallest amount of serum which protects 50 per cent of mice against 100 fatal doses of Type 3 pneumococci.)

**Agglutinins** 0 = absent 2 4 etc = greatest dilution of serum in which floccular agglutination occurred

**Protection** The numbers represent the largest number of fatal doses of Type 3 pneumococci which mice survived with the simultaneous injection of 0.2 cc. of serum

**Phag index** Average number of diplococci per polymorphonuclear leukocyte in the phagocytic test.

**Pn killing** Maximum number of Type 3 pneumococci which were killed in 0.5 cc of fresh defibrinated blood

#### Abbreviations

P.A.B.S. = para aminobenzenesulfonamide (sulfanilamide)

SP = sputum

P.N. III = pneumococcus Type 3

L.P.N. = lobar pneumonia

BR. = atypical (broncho-) pneumonia

R. U. M. = right upper and middle lobes

L. L. = left lower lobe

R. L. = right lower lobe etc

S.H. = *Streptococcus hemolyticus*

S.A.U. = *Staphylococcus aureus*

H.I.N.F. = *Haemophilus influenzae*

HGB = hemoglobin (Sahli)

T = transfusion the number represents the amount of blood in cubic centimeters

† = expired.

were made are shown in the accompanying charts. These include all the patients treated with specific serum, either alone (Cases 1-4) or in addition to sulfanilamide (Cases 5-17), and also a few of the patients who received only the drug (Cases 18-30). The essential features of the remaining patients who were treated with sulfanilamide alone (Cases 31-56) are listed in Table 1.

There were 24 deaths among the 56 treated cases, a mortality of 43 per cent. During the two-year period from July, 1936, to July, 1938, there were 135 patients with pneumococcus Type 3 pneumonia who received neither serum nor sulfanilamide, and 64 of these patients died, a mortality of 47 per cent. The death rates in these

In interpreting these data it is important to bear in mind certain features in the cases chosen for treatment. It has been pointed out previously that the supply of serums available during the period of this study was limited and included a number of experimental lots of low or unknown potency. In a number of cases, serum administration had to be discontinued because the available supply was exhausted or because of untoward reactions. All these cases have been included in the figures presented. Furthermore, in certain of the cases the bacteriological and autopsy findings indicated that the failures in treatment were associated with other factors not directly related to the Type 3 pneumococcus infection. It is of interest, therefore, to note

Table 2 Summary of Death Rates from Pneumococcus Type 3 Pneumonia, Boston City Hospital, 1936-38

Cases in which the type was obtained at autopsy are omitted (there were 20 such cases).

†Four cases received serum alone; they are indicated by the superscripts.

two groups of cases are shown in Table 2, the cases being arranged in different age groups and according to the results of blood cultures. Bacteremia was more frequent in the treated cases, particularly among those who received both serum and sulfanilamide. The death rate in the 37 non-bacteremic patients who received serum or sulfanilamide or both was 24 per cent, as compared with a 38 per cent mortality in 85 cases treated without these agents. There was a single recovery among the 26 untreated bacteremic patients, whereas 3 of the 16 treated bacteremic patients recovered. Each of the latter 3 survivals received sulfanilamide alone.

Taken as a whole, the duration of the acute disease was somewhat longer in the patients treated with serum or sulfanilamide or both than in the untreated cases (Fig. 4). This was true for both the fatal and the recovered cases. The average duration of the acute illness in the patients who recovered was 7.8 and 7.3 days for the treated and untreated cases respectively. The average duration of the disease in the fatal cases which received serum or sulfanilamide or both was 11.3 days, as compared with 9.1 days in the untreated fatal cases.

briefly some of the more important features of the treated cases.

Cases Treated with Serum Alone. Only 4 patients were treated with specific serum alone and

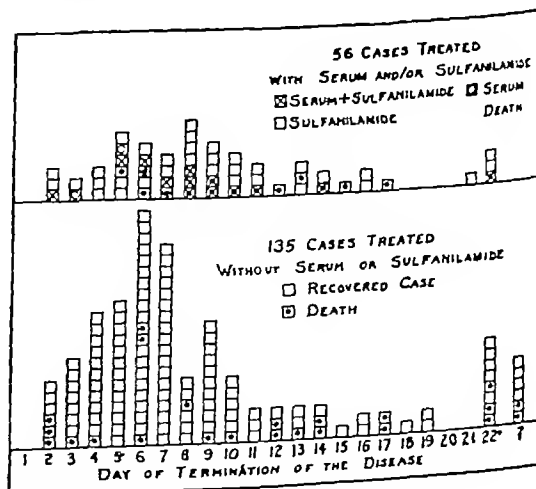

Figure 4 Duration of Disease in Type 3 Pneumococcus Pneumonia

2 of them died (Fig. 1). In Case 1 the dose was obviously inadequate in view of the severe infec-

tion. Antibodies could not be demonstrated in the blood after treatment, and heavy bacteremia ensued. In the other patients a balance of antibodies was readily established and maintained. In Case 2, serum administration was accompanied by moderately severe chills and was followed by the development of intractable pulmonary edema, the pneumonia extended in spite of sterile blood cultures and the presence of a balance of antibodies. The other 2 patients had prompt clinical improvement.

*Case Treated with Serum and Sulfanilamide*  
There were 7 deaths among the 13 patients who received the combined therapy (Fig 2). Bacteremia was demonstrated in 6 of these fatal cases and was of severe grade in 3. In only 1 of the 7 fatal cases was serum treatment begun before the fifth day. In Case 5, treatment was started on the eighth day, a blood culture taken before the first dose of serum was given yielded 3000 colonies of Type 3 pneumococci per cubic centimeter and the patient died within a few hours. In Case 6 and Case 7 the amounts of serum given were not sufficient to establish a balance of specific antibodies, and bacteremia was present irregularly after the serum had been given and while the patients were receiving sulfanilamide. In Case 6 blood cultures were sterile during the last two days of life, and at autopsy no Type 3 pneumococci were found in cultures from the lungs.

In 3 bacteremic patients (Cases 8, 9 and 11) a balance of antibodies was established and maintained and the Type 3 infection was apparently controlled. One of these patients (Case 8) died in uremia a week after apparent recovery from the pneumonia. The second patient (Case 9) had a cerebral hemorrhage and hemiplegia on the second day after treatment and after an apparent crisis, death occurring two days later. No pneumococci could be recovered from the lungs of this patient. The third patient (Case 11) had a heavy bacteremia. This patient lived for twenty days under intensive treatment, during which severe anemia developed and required several transfusions. Repeated blood cultures taken after treatment were sterile. Autopsy revealed numerous large abscess cavities, the contents of which yielded Type 3 pneumococcus and *Staphylococcus aureus* on culture.

In Case 10, circulatory collapse and pulmonary edema developed on the second day after treatment, and persisted. Blood cultures taken before and after treatment were sterile, but the patient had a high fever, delirium and marked prostration at the time treatment was begun.

The 6 patients (Cases 12-17) who recovered fol-

lowing combined therapy all had sterile blood cultures throughout the course of their disease. They showed marked clinical improvement with respect to their pneumonia within a few hours after serum treatment was given. A balance of antibodies was demonstrated in each case. In 4 of these 6 cases, treatment was begun before the fifth day of the disease.

*Patients Treated with Sulfanilamide Alone*  
The 13 patients of this group in whom immunological studies were made are of special interest and should be considered separately (Fig 3). Four of these 13 patients died, including 2 who had positive blood cultures. Treatment with the drug was begun on the fourth day in 1 of these patients (Case 20) and on the sixth day or later in the other 3. Following treatment with the drug, 1 of the bacteremic patients (Case 18) developed a balance of type-specific antibodies, but a hemolytic *Staphylococcus aureus* was recovered from two blood cultures subsequently. A second patient (Case 21) had sterile blood cultures throughout and died after eight days of treatment. Cultures of the lungs yielded streptococci, staphylococci and influenza bacilli, but no Type 3 pneumococci.

Three bacteremic patients recovered following sulfanilamide therapy. One of them (Case 22) was given a single trial dose of 2 cc of serum on the third day of his disease. This was followed by a severe chill with a rise in temperature to 107°F., and serum therapy was discontinued. Blood cultures taken before this serum injection and again on the following day just prior to the first dose of sulfanilamide were both positive for Type 3 pneumococci. Crisis occurred on the fifth day. Pneumococcal activity was demonstrated in this patient's blood on one occasion after crisis, but specific agglutinins and mouse protective antibodies for the homologous type of pneumococcus could not be demonstrated. The second patient (Case 23) had a sterile blood culture on the third day, but the one taken the next day, just before beginning sulfanilamide therapy, was positive for Type 3 pneumococci. Crisis two days later was followed by the development of specific agglutinins and protective antibodies, but fever persisted during the next two weeks, presumably due to the continued drug therapy. These last 2 patients developed moderately severe anemia with drops in hemoglobin of 40 and 32 per cent respectively, after a week or more of treatment. The third patient (Case 24) had transient bacteremia, but a blood culture taken on the ninth day just before sulfanilamide treatment was begun was sterile. Crisis associated with a high titer of specific antibodies occurred on the following day.

Of the 6 non-bacteremic patients (Cases 25-30) in this group who recovered 4 developed homologous antibodies. One (Case 29) of 2 patients in whom such antibodies did not develop had asthma and atypical pneumonia with only slight pulmonary involvement, but the other (Case 27) had lobar pneumonia and was acutely ill and irrational for several days.

The remaining 26 cases treated with sulfanilamide alone are listed in Table 1. There were 4 bacteremic patients among them and all 4 died. Three of them were treated for only one day. In the fourth patient (Case 34) treatment was begun on the third day, all subsequent blood cultures were sterile, the patient developed anemia and nitrogen retention and died, in spite of repeated transfusions. There were 7 other deaths in this group, 5 in patients with sterile blood cultures and 2 in those from whom blood cultures were not made. Three of these 7 deaths occurred on the fifth day of the disease and after only a single day of sulfanilamide treatment. Death was delayed a week or more in the other 4 cases.

Among the 15 patients in this group who recovered, crisis was prompt in 6 cases, including 4 (Cases 31, 39, 46 and 48) in which treatment was begun on or before the fourth day. In the remaining cases recovery was delayed from two to ten or more days.

#### DISCUSSION

The clinical results, when considered from the point of view of the effect of treatment on the death rate and on the duration of the acute disease, are not very impressive. Scrutinized more closely, however, they indicate that we are dealing with two useful therapeutic agents. The appreciably lower death rate in the non-bacteremic cases suggests that blood invasion may have been prevented by treatment in some of them. The 3 bacteremic recoveries are of some interest because of the rarity with which recoveries are encountered in pneumonias with Type 3 pneumococcus bacteremia, even of low grade. It is possible that 2 of these patients would have recovered spontaneously, since antibodies developed after the sulfanilamide therapy, but this was not true in the third case.

Furthermore, the bacteriological, immunological and autopsy findings in some of the fatal cases strongly suggest that both the drug and the antiserum, but particularly the combination of the two, had marked curative effect on the Type 3 in-

fection. Adequate causes for death, apart from the specific infection, were found in an appreciable number of these fatal cases. In addition, we must consider the severity of the cases chosen for treatment, the experimental character, inadequate amounts and low potency of the serums available during this study, and the fact that we were dealing with a group of old and severely ill patients in whom sulfanilamide therapy is frequently difficult to control properly. The lots of serum which became available toward the end of this study and which have been in use since have been considerably higher in potency and, aside from occasional mild chills, have not produced severe untoward reactions. All these considerations suggest that specific serum and sulfanilamide, both used in proper amounts, should give good therapeutic results and appreciably lower the death rate.

The studies are being continued at the Boston City Hospital. The action of sulfapyridine and its effect on the course of Type 3 pneumococcus pneumonia is being assessed. While it is yet too soon to draw final conclusions, the findings suggest that the combination of specific antipneumococcus rabbit serum and sulfapyridine exerts an optimum effect, both in vitro and in the patient.

#### CONCLUSIONS

The pertinent data concerning 56 cases of pneumococcus Type 3 pneumonia treated with specific antipneumococcus rabbit serums and sulfanilamide, separately or in combination, are presented.

While the death rate was not significantly lowered in the entire group of treated cases, a consideration of the effect of treatment in the individual cases, the bacteriological and immunological findings, and the circumstances surrounding some of the unfavorable results all suggest that the combination of specific serum and sulfanilamide is a useful and effective means of combating pneumococcus Type 3 pneumonia.

## COMMENTS ON CLINICAL STUDIES IN PATIENTS WITH KIDNEY DISEASES

GEORGE C PRATHER, M.D \*

BOSTON

DR DAVID MacKENZIE, of Montreal, recently stated that, in the field of medicine, "the space between knowledge and how to use it is still wide." One's knowledge of all the possible types of diseases causing symptoms in a patient may be adequate, but if that knowledge is not applied in reaching a diagnosis, the patient is being treated on the basis of a probable diagnosis rather than on that of a certain one.

At times, symptoms and signs caused by surgical disease of the genitourinary tract closely resemble those of one of the so-called medical conditions of the kidney. As an illustration, let me relate the recent experience of a young man who, because of albuminuria and microscopic hematuria, had been diagnosed by his physician as suffering from chronic nephritis. During a two-year period, in an effort to exclude all foci of infection, he had undergone tonsillectomy and the extraction of several teeth. Unfortunately, after these procedures the urinary findings remained unchanged. Eventually, urological study revealed a moderate-sized stone in the right renal pelvis. Removal of the stone allowed the patient a urine free of albumin and microscopic blood, and relieved his mind concerning the hazards of Bright's disease. Many individuals with the same urinary findings may, of course, be correctly diagnosed medically as victims of nephritis. Yet it is better to use one's knowledge of all possible causes of a certain syndrome and thus to obtain an accurate diagnosis, so that one can be as sure as possible that the treatment or regime advised is the best that is known. Today such study as may be necessary can usually be provided without undue risk or expense to the patient.

Among the commoner signs and symptoms which may indicate kidney disease are pain, albuminuria, pyuria and hematuria. One of the most important questions that we must decide is, Under what circumstances is it wise to consider the kidney condition purely a medical one? Or, to put it differently, when is urological study indicated? How should this be done?

The typical case of renal colic, with its customary radiation of pain toward the inguinal region and external genitalia, does not offer a serious clinical diagnostic problem, except for

the physician who attempts to tell the patient how large the stone is, where it is in the course of the renal pelvis or ureter and whether it will pass. It is difficult to estimate the size of a stone without x-ray evidence. In general, large kidney stones give rise to less acute pain than do small ones which are in process of descent. What is a rational course of study in the diagnosis of a renal or ureteral stone? The clinical diagnosis can, of course, be inferred from the acute colicky type of pain and from microscopic hematuria. We must remember, however, that any renal cause of hematuria can produce a colicky type of pain simply as a result of blood or a blood clot which descends the ureter. The pain of renal colic is therefore not positive evidence of stone. Even though all symptoms subside, it is wise, I believe, to obtain a plain film of the kidney and bladder regions, as well as intravenous pyelography, within seven days of the renal colic. If pain does not subside with morphine in the course of three or four hours, or if repeated attacks of colic ensue, more immediate x-ray study is indicated. Intravenous pyelography does not need to be done by the urologist alone, the procedure can be used freely by all those who practice medicine, if the following limitations are realized. First, generally speaking the contrast shadows are not so sharp as with retrograde filling. Secondly, poor or mediocre filling of the pelvis and calices may, because of this lack of contrast, give the impression that the kidney is probably normal, it is dangerous in these circumstances to assume its normalcy. Thirdly, the method when used in the diagnosis of hematuria does not give so accurate a picture of bladder disease as does cystoscopy. Fourthly, when intravenous pyelography is used for diagnosis in pyuria, the advantage it offers for determining the source of the infection remains a probability rather than a certainty.

When recent renal colic has occurred, only a few precautions need to be taken for intravenous pyelography. Restriction of fluids for six hours preceding the injection is advisable, the bowel should be as free as possible of gas, and inquiry should be made as to any allergic tendency. When properly performed, this study should give indication of the size and location of a stone, as well as of interference with kidney function.

We all examine individuals who have a dull,

Assistant in anatomy Harvard Medical School assistant urologist, Beth Israel and Boston Lying in hospitals

sometimes intermittent pain in the kidney region or the upper quadrant of the abdomen, or the so-called pain along the course of the ureter, pain which may be due to renal, ureteral, abdominal or perhaps pelvic disease. Suppose that a carefully taken history, abdominal palpation, pelvic and rectal examinations and urine analysis fail to clinch the diagnosis. It is possible or probable that a kidney is the source of the trouble, it is also possible that the bowel is responsible. How should one proceed? In such a case, if the urine sediment under microscopic examination shows no evidence of blood or infection, I should again prefer a plain film of the kidney, ureter and bladder region, with intravenous pyelography, followed by a gastrointestinal series, barium enema or other studies, if necessary. If the gastrointestinal studies are done first, opaque masses can be found by x-ray, sometimes for a period of days afterward. This condition holds true even following catharsis and enemas, and ruins any chance of immediate urological study. The reverse does not hold true: urological x-ray photography will not interfere with the making of abdominal studies on the following day. Therefore, when a differential diagnosis is considered, urological study should precede gastrointestinal study in order to save the patient time, as well as expense, if he is in a hospital. With obscure pain due to hydronephrosis, the intravenous pyelogram has an excellent chance of indicating the diagnosis. Retrograde pyelography, I believe, is preferable, however, in cases of obscure pain which show abnormalities in the urine sediment. Divided catheter specimens, split functions, and so forth, allow one to interpret the findings more accurately than can usually be done by intravenous pyelography.

Hematuria is a very important finding. The amount of blood is not necessarily so important. The presence of blood in the urine, either in gross or microscopic amounts, indicates serious disease of the urinary tract unless complete examination proves otherwise. To the physician, hematuria brings to mind many possibilities, such as acute nephritis, trauma, hemorrhagic infection, tumor, stone or tuberculosis in the urinary tract and blood dyscrasias. Urological study of hematuria should not necessarily be done on the day on which it occurs or is found. Two conditions which should be ruled out before cystoscopic study is undertaken are acute nephritis and hemorrhagic infection of the lower urinary tract. Clinical findings in acute nephritis are well known. Hemorrhagic cystitis, while less common, is a distinct clinical entity causing extreme bladder symptoms with gross hematuria at the onset of the infection. Bacteria and leukocytes

can be demonstrated in the urine along with erythrocytes. As the infection is often confined to the lower urinary tract, ureteral catheterization may introduce virulent bacteria into the kidneys and lead to pyelitis. If one allows the cystitis to subside with proper treatment for two or three weeks, cystoscopic study can be performed without risk. Often it is only microscopic hematuria that gives the lead to serious renal or bladder disease. The type of disease can often be diagnosed only from the anatomical and physiological findings—namely by cystoscopic, pyelographic and functional studies. It is true that the patient with the typical picture of acute nephritis is not a proper subject for pyelographic study, but some patients have been observed for months or longer as having a form of chronic nephritis with a very small trace of albumin and microscopic hematuria, or a low grade urinary infection with the slightest possible trace of albumin, even though the condition is actually due to some renal or bladder condition which can be corrected. The patient who has hematuria probably due to some medical condition of the kidney will not be harmed by x-ray study, intravenous pyelogram, bladder cystoscopy or retrograde pyelogram provided that renal function has not been impaired to the extent of elevation of the nonprotein nitrogen of the blood. If the findings of medical disease of the kidneys are confirmed by these methods, certainly the physician can treat his patient with all the more assurance. Just how soon complete study of the patient with hematuria is warranted is a question which is impossible to answer for all occasions, but in a given case either a capable physician or a urologist should be able to tell. In general, one should make an investigation—that is, complete renal and bladder study—as soon as acute nephritis and acute urinary infection have been ruled out. It is true that waiting for the next evidence of hematuria before investigation is a most dangerous practice as concerns the well-being of the patient.

Patients with pyuria or bacteruria constitute a definite group in any physician's practice. The old routine under which urotropin and sodium acid phosphate were prescribed on the discovery of pus cells in the urine with the expectation that the urine would automatically become crystal clear, is about as modern as a low tax rate.

It is true that many acute urinary tract infections prove self-limited if given reasonable medical treatment consisting of rest and generous quantities of liquids. The patient's history, symptoms and course of fever help to indicate whether the inflammatory process originated in the upper or the lower urinary tract. We know that in the febrile state, it is unwise to use mandelic acid,

with the necessary restriction of fluids, instead, we believe that the taking of liquids up to 4500 cc per day, combined with rest, is the best program. Mild alkalis such as potassium citrate and sodium bicarbonate are better tolerated than is urotropin, with its resultant acidification. It is not yet certain whether or not sulfanilamide should be used in acute, febrile, urinary infections. We believe that for progress to be considered satisfactory the temperature must be at or near normal within seven to ten days after the onset of the infection, and that if a spontaneous cure from the acute attack is to be accomplished the urine must be sterile within a month.

Three conditions in regard to infection of the urinary tract are indications for urological study: first, acute pyelitis which causes a fever for longer than ten days, second, any pyuria of longer than sixty days' duration, and third, the history or suspicion of stone and infection. In the case of prolonged fever, associated disease interfering with proper urinary drainage is most likely, or instead some such complication as true cortical infection or perinephric abscess may occur. In the case of chronic pyuria without a bladder residual, one might say, Why bother with urological study? Merely give an effective urinary antiseptic. Such a program, while feasible, ignores the anatomical condition of a kidney which because of some fundamental disease is harboring infection—disease which may be gradually interfering with the function of the kidney, and therefore needs correction, in addition to relief of the urinary infection. It is preferable to know whether there is such underlying disease before treating a chronic urinary infection. Tuberculosis, infected hydronephrosis, and so forth, may in that event be diagnosed and corrected before too great damage has been done. The presence of an obstructing ureteral or renal calculus with urinary infection always warrants surgical treatment.

Tuberculosis of the urinary tract may be considered along with pyuria. When can the clinician suspect tuberculosis rather than one of the commoner urinary infections? The onset of symptoms, of course, may be identical with a nonspecific pyelitis or cystitis, or may begin with renal pain. The presence of red blood cells in a specimen of urine containing leukocytes is a suspicious finding,

a catheterized specimen showing pyuria but no bacilli or cocci also suggests tuberculosis. The urine in renal tuberculosis is nearly always acid unless there is a superimposed secondary urinary infection.

Is tuberculosis of the urinary tract primarily a medical or a surgical condition? I believe it is nearly always both. We know that renal tuberculosis is secondary to a tuberculous focus in some other part of the body, although that focus cannot always be demonstrated by clinical examination. The entrance of this disease into the urinary tract is at times evident in only one kidney. Sooner or later both kidneys become involved. If on cystoscopic study only one kidney is found to be infected, it is possible to cure the disease by nephrectomy on the diseased side. If the disease is bilateral, surgery is generally contraindicated. Seldom is renal tuberculosis cured by medical treatment, although symptoms may be improved and the progress of the disease checked. Intelligent handling of this condition requires, I believe, the services of a urologist who knows the limitations as well as the benefits of surgery, and recognizes the value of preoperative treatment. The services of the medical man in judging the condition of the patient's lungs and his power of resistance and in determining the opportune time for surgery, as well as in supervising the regimen, are likewise necessary.

Finally, mention must be made of a subject about which relatively little is known but which is sure to command an increasing amount of attention in the future. Hypertension caused by unilateral renal disease or ischemia is a fascinating subject, a few case reports are appearing which describe how patients with hypertension apparently due to this form of kidney disease have been improved or relieved by operation on the affected kidney. Most cases of hypertension do not, so far as we know, fall into the group which can be improved by renal surgery, yet anatomical and physiological studies of the kidneys in patients with hypertension may enable one to find the occasional patient who can be helped by urological surgery.

Only by maintaining an alert attitude toward all phases of renal disease can the urologist give patients and physicians the best advice in each individual problem.

It is true that many acute urinary tract infections prove self-limited if given reasonable medical treatment consisting of rest and generous quantities of liquids. The patient's history, symptoms and course of fever help to indicate whether the inflammatory process originated in the upper or the lower urinary tract. We know that in the febrile state, it is unwise to use mandelic acid,

the cavity to be larger than before and revealed a bronchial fistula (Figs 1 and 2) \* On February 25, a flat film of the chest showed thickened pleura and very little fluid in the left chest. Injection of 4 cc. of lipiodol showed the pleural cavity and bronchial fistula to be smaller. On March 19, a 20-cc. injection of lipiodol showed the cavity to be larger and the fistula prominent. Treatment was continued, and the cavity eventually healed completely

*Comment* This case demonstrates how inconclusive flat x ray films of the chest may be in estimating the size of an empyema cavity. If lipiodol had not been used, the drainage tube might have been removed when the cavity held 12 cc. measured by irrigation. In addition, the bronchial fistula would not have been revealed

*Case 2* M. S., a 28-year-old woman, entered the hospital on January 18, 1937, or 4 weeks after the onset of pneumonia. On the 7th day left thoracentesis revealed thick, odorless, greenish pus containing Type 3 pneumococci. X ray of the chest was consistent with fluid in the left chest. The following day, under Cyclopropane anesthesia, a rib resection was performed and 250 cc. of pus was obtained. The cavity was irrigated with salt solution and then Dakin's solution. On March 1, the cavity held 4 cc. measured by irrigation and injection of lipiodol showed a very small pocket. The tube was therefore removed, and the wound healed by March 28. The patient remained well, and an x ray film taken on February 25, 1938, revealed a normal chest.

*Comment* This case is included because of the corroborative evidence given by the injection of lipiodol to the effect that the tube could be removed with impunity

*Case 3* E. B., a 37-year-old man, was admitted to the hospital on February 4, 1937, with a history of pneumonia

fluid in the right chest. On February 29, under Cyclopropane anesthesia, rib resection was performed and a large amount of pus was obtained. On March 29, injection of lipiodol showed a cavity measuring 4 by 7 cm. by x ray

Figure 4 Lateral View of Chest Shown in Figure 3  
This demonstrates the true extent of the sinus

On April 8, the cavity held 10 cc. measured by irrigation, and the tube was removed. The patient remained well until 7 months later, when the incision reopened and

of 10 days duration. On February 22, thoracentesis yielded 800 cc. of thick, greenish pus, cultures showed Type 1 pneumococci. An x ray film was consistent with

In some cases lipiodol fillings have been outlined on the x ray plates in order to give sharp contrast.

Figure 5 Lipiodol Filling, with Obliteration of the Empyema Pocket

a draining sinus resulted. Injection of lipiodol showed a definite pocket, and a tube was inserted (Figs. 3 and 4). Three weeks later the tube was removed after injection of lipiodol revealed a very small pocket (Fig 5). The patient remained perfectly well.

## INJECTION OF LIPIODOL AS A GUIDE IN ESTIMATING THE HEALING OF ACUTE EMPYEMA CAVITIES\*

HENRY L. CABITT, MD,† AND ALFRED HURWITZ, MD‡

BOSTON

**I**N a discussion of the treatment of acute empyema, Graham, Singer and Ballou<sup>1</sup> have stated that there are three cardinal principles maintenance of nutrition, drainage, but with careful avoidance of an open pneumothorax during the period of active pneumonia, and early sterilization and obliteration of the cavity. We propose to discuss the difficulties in determining the obliteration of an acute empyema cavity and to emphasize the importance of lipiodol in this determination

an empyema cavity by irrigation alone, or even by the interpretation of x-ray films of the chest, may be erroneous, and that the injection of lipiodol, before removal of the tube, is necessary in order to show the size, extent and location of the cavity. The 4 cases that follow have been selected to justify our contention.

*Case 1* B. M., a 38-year-old man, was admitted to the Beth Israel Hospital on November 15, 1937, or 7 weeks after the onset of pneumonia. Thoracentesis yielded thick, gray green, odorless pus, a smear showed a few polymorphonuclear leukocytes but no bacteria. Both aerobic and anaerobic cultures were negative. X-ray films at this time were consistent with fluid in the left chest. On

Figure 1. Lipiodol Filling, Showing an Empyema Pocket and a Bronchial Fistula

*There is lipiodol in the contralateral upper lobe*

We know that this obvious and logical procedure has been employed by some surgeons, but a careful perusal of the literature has revealed no general acceptance of it. On the other hand, many surgeons have removed the drainage tube from an acute empyema cavity when it measured 10 cc. or less on irrigation. It is also a known fact that a few acute empyema cavities thus measured have recurred with a residual pus pocket, and some have progressed to chronic empyema.

We shall demonstrate that the measurement of

Figure 2. Lateral View of Chest Shown in Figure 1

November 18, rib resection was performed under Cyclopropane anesthesia and 1000 cc. of pus was obtained. Two rubber tubes were inserted and the cavity was irrigated postoperatively, with salt solution administered for 2 days and Dakin's solution thereafter. The patient made an uneventful convalescence. On December 16, a flat film of the chest was interpreted as showing thickened pleura and a slight degree of pneumonitis in the left lung, with evidence of a small amount of fluid in the pleural cavity. The cavity held only 30 cc. on irrigation, but with lipiodol a large cavity was demonstrated. On January 4, an injection of 12 cc. of lipiodol still revealed a large cavity, although it was smaller than that noted previously. On January 21, a flat film of the chest revealed a small amount of fluid at the left base, other than this there was nothing worthy of note. Injection of 20 cc. of lipiodol showed

\*From the Thoracic Clinic of the Beth Israel Hospital

†Assistant in surgery Tufts College Medical School surgeon to the Thoracic Clinic Beth Israel Hospital

‡Assistant in surgery Harvard Medical School assistant outpatient surgeon Beth Israel Hospital

*Comment* In this case the drainage tube was removed from the right pleural space on the first admission because the cavity held only 3 cc. measured by irrigation. No lipiodol had been injected at that time. Although several months elapsed before the recurrence of the empyema, it seems unlikely that this complication would have occurred if the cavity had been obliterated at the time of the first admission.

When the time approaches for the removal of the tube from the pleural space, as indicated by the general condition of the patient and the diminution of drainage from the pleural cavity, lipiodol should be introduced through the tube. We ordinarily use a 40 per cent solution. In large cavities, owing to the expense involved, we dilute the lipiodol with mineral oil, and have thus obtained satisfactory films. In introducing the lipiodol, excessive pressure should be avoided. The patient is placed with the affected side uppermost so that the lipiodol will flow in by gravity. In order to demonstrate the presence or absence of a bronchial fistula, the patient is instructed to close his mouth tightly, hold his nose firmly and take a deep breath.

The instillation of lipiodol is the only exact method for determining the size, shape and location of an empyema cavity. On numerous occasions we have been misled concerning the size of a cavity by the interpretation of flat films of the chest, and also by the simple introduction of salt solution. The quantitative measurements are often meaningless because the fluid content of the cavity is not evacuated completely before the introduction of the measuring fluid. Attempts have been made to empty these cavities before injection by postural drainage, and even by aspiration of the cavity fluid through a catheter, but without success. This explains the discrepancy between the size of the cavity as seen by x-ray after the instillation of lipiodol and the measurements by saline irrigation.

In one of our cases (Case 1) injection of lipiodol demonstrated the presence of an unexpected bronchial fistula. It had not been noted previously during the course of daily irrigations with salt solution.

Removal of the tube should take place only after the injection of lipiodol reveals a well-obliterated pleural space. For example, in Case 3 the tube was removed without further lipiodol checkup a week after injection of lipiodol had shown a fairly extensive cavity. This patient had an incompletely drained pleural space, even though it held only a few cubic centimeters of saline at the time of the removal of the tube. This case also tends to refute Ransohoff and Heiman's<sup>2</sup> contention that since lipiodol acts as an obliterating agent it is safe to remove the tube even in the presence of a large cavity.

The incidence of recurrent empyema should be reduced by a more general adoption of this procedure. Case 4 has a possible bearing on this point, the patient had a recurrence of empyema fifteen months after drainage, even though the flat x-ray films taken in the interim were negative. There was no instillation of lipiodol before removal of the tube. It seems reasonable to assume that if lipiodol had been used and had shown complete obliteration of the cavity at the time of the first discharge, the possibility of recurrence would have been extremely remote.

#### CONCLUSIONS

Flat films of the chest are often misleading in determining the size of the pleural space after drainage of an empyema cavity.

The amount of salt solution employed in measuring a cavity is usually much less than the actual size of the cavity.

X-ray films taken after the instillation of lipiodol are extremely accurate in determining the size, shape and position of the cavity and in ascertaining the proper time for removal of the drainage tube.

A more general adoption of this method as a routine procedure should lead to a lessened morbidity and a diminution in the incidence of chronic empyema.

these, as in all others, the degree of symptomatic peripheral recovery depends on the variety of tissue that has failed to fuse. Thus meningo- or encephalomyelocele has the least and the spina bifida occulta the most favorable outcome, regardless of the type of therapy

#### INFECTION

Infectious processes that involve the central nervous system might be supposed to be outside the realm of neurosurgery. Nevertheless, it is true that because they frequently occur as complications of otherwise uninfected conditions, a knowledge of their characteristics is necessary for the neurosurgeon

*Meningitis* Non-specific meningitis is still treated most successfully by as near an approach to constant lumbar drainage as is feasible, plus the administration of large amounts of fluid, preferably by mouth or, if that is not possible, by any other method. Constant lumbar drainage by either needles or indwelling ureteral catheters has not yet proved practical. Proved or suspected infections with *Streptococcus hemolyticus*,<sup>6</sup> the meningococcus,<sup>7</sup> the pneumococcus<sup>8</sup> and probably the influenza bacillus should be treated by sufficient sulfanilamide by mouth to insure promptly and to maintain constantly a 10 mg per cent or higher concentration of the drug in the blood at all times. Appropriate antiserums must also be used, and care taken to anticipate any toxic effect of the sulfanilamide by daily red and white blood-cell counts and the administration of sodium bicarbonate

Meningitis following trauma is found, according to Courville and Platner,<sup>9</sup> to vary from 2.3 to 10 per cent in various series of autopsies, their figure being 6. The figures were collected from groups which ranged from 432 cases for the lowest figure to 1261 for their own. My<sup>10</sup> figures, as obtained from 1203 hospitalized patients, gave an incidence of 0.4 per cent. If only the fatalities were considered the incidence rose to 2 per cent. It seems justifiable to conclude that treatment accorded the patients in the series with the high incidences might have been susceptible of improvement

*Brain abscess* This is a much-discussed problem so far as its treatment is concerned. I believe that the best evidence is to the effect that when the abscess is relatively young and heavily encapsulated, repeated tapping and inadequate drainage through a small rubber tube are equivalent to neglect. The preferred method should, if possible, be carried out in two stages. At the first stage, the bony opening is made, the abscess located and the meninges at the edge of the skull

defect sealed with the cautery or by an iodine-soaked pack. At the second stage, depending on its relation to the surface of the brain and its age, the abscess is opened and drained, marsupialized<sup>11</sup> or excised. Drainage is by means of loose packing with gauze around one or two rubber tubes,<sup>12, 13</sup> through a Mosher<sup>14</sup> copper-wire-gauze cone drain or by gauze pack alone, as described by King.<sup>15</sup> If the abscess is non-encapsulated or encephalitic in type, there is no method of treatment which approaches that of King<sup>16</sup> in efficiency or safety. Metastatic abscesses are usually considered to be multiple, but Courville<sup>17</sup> has made the statement that they are single in 50 per cent of the cases

*Osteomyelitis of the skull* Although Adson<sup>18</sup> advocates only sequestrectomy and removal of all dead bone in osteomyelitis of the skull, the balance of opinion is against him. As emphasized by Hill,<sup>18</sup> the generally preferred method is to go farther than this and excise all dead bone through the adjoining viable edges, the excision to include not only the sequestra in the area but all other bone as well

*Epidural spinal infections* Of these the commonest is epidural spinal abscess. According to the experience of Cohen<sup>19</sup> and others, the history of a sudden attack of acute excruciating pain in the back, followed by a rise in temperature and the onset of tingling, numbness and weakness in the legs with sensory and motor paralysis, together with bladder difficulties in the next few days or weeks, is typical. When a source for a septic metastasis and a cerebrospinal-fluid block at lumbar puncture can be demonstrated, or pus is found in the spinal epidural sac, laminectomy and surgical drainage are imperative and, in fact, often overdue. The prognosis improves directly with the promptness of operation and, with the aid of tidal drainage, may be good even in those cases in which the paralysis is already relatively far advanced

#### INJURIES TO THE CENTRAL NERVOUS SYSTEM

*Craniocerebral injuries* With only rare exceptions, it is now generally agreed that the preferred treatment of the fundamental non-operable type of craniocerebral injury is by lumbar decompression combined with judicious dehydration. Subtemporal decompression is practically never indicated for its decompressive effect only, although exploratory trephination is well established as a diagnostic requirement.<sup>10</sup> Of the operable group, it is becoming increasingly evident that the subdural hematoma is much commoner than has been supposed and that the final diagnosis can only be made by means of exploratory trephination. It is therefore greatly to be regretted that Kaump and

## REPORT ON MEDICAL PROGRESS

## NEUROSURGERY

DONALD MUNRO, M.D.\*

BOSTON

TO RECORD progress in neurosurgery is to measure progress in medicine in general. Specialties are limited in name only, and then only because the specialist has sacrificed his general medical knowledge in favor of superknowledge about one single subject. With this superknowledge goes ignorance, and the specialist becomes a specialist not by virtue of what he knows but rather by virtue of what he knows he does not know. It is therefore the progress that is made in the fields outside, quite as much as the changes that take place within, that affect the advancement of a specialty. A discussion of the year-by-year alterations that have taken place within the field of neurosurgery cannot be a measure of progress but is rather a critique of methods and ideas.

CONGENITAL STATES AND THOSE ARISING  
AT OF JUST AFTER BIRTH

*Cyanosis of the newborn* In its neurological aspect the conception, now well established, that cyanosis within physiologic limits is the normal condition of the newborn, is second only in importance to the establishment of the fact that asphyxia, which is not cyanosis but pathologic anoxemia, is the fundamental factor in the determination of the degree of acute brain injury.<sup>1</sup> Treatment based on this concept determines, at the last analysis, the amount of future invalidism. If carried to its logical conclusion, it is apparent that lumbar decompression, supplemented by diagnostic subdural puncture and, if necessary, by trans-temporal trephination and appropriate dehydration, is the only acceptable treatment for intracranial hemorrhage of the newborn. The possibility of an associated hemorrhagic diathesis is cared for by the routine intravenous administration of parental whole blood in any vein except the superior sagittal sinus.

*Porencephaly* This condition in which there occurs "a defect in the cerebral or cerebellar structure appearing as a cystlike cavity communicating with the ventricles or separated from them by only a thin layer of brain tissue, covered on the outside by the pia arachnoid and filled with a clear colorless fluid,"<sup>2</sup> may be the result of birth injury, is frequently associated with convulsive seizures

later in life and has commonly been regarded as not amenable to treatment from the point of view of relief of symptoms. My experience with 2 cases and Patten's<sup>3</sup> similar experience makes the outlook for these patients much more hopeful. There is no doubt but that in view of this evidence, anyone who is proved to have a porencephalic cyst should have a craniotomy and a destruction of the surface of the cyst cavity. The diagnosis is usually made by an encephalogram. Both examination and treatment should be instituted early in order to avoid the excessive cortical atrophy that otherwise develops.

*Communicating hydrocephalus* Dandy<sup>4</sup> has again drawn the attention of the medical public to Putnam's work in the treatment of communicating hydrocephalus. The latter's therapy called for destruction of the choroid plexus in the two lateral ventricles and possibly also in the lateral recesses of the fourth ventricle. It is the only method that offers any hope for these invalids, but too much should not be expected of it.

*Athetosis* Section of the extrapyramidal tracts in the spinal cord as a means of relieving athetosis<sup>5</sup> occupies a definite place in our armamentarium against this dreadful form of invalidism. While not yet curative, there is reason to hope that, with early diagnosis and treatment, more may be accomplished than mere relief of invalidism. The procedure is highly technical and should be undertaken only by one well trained in neurosurgery.

*Spina bifida* Although spina bifidas may be successfully closed, a well baby does not necessarily follow. A high percentage of these children develop an acute hydrocephalus which vitiates the surgeon's otherwise successful work. Penfield and Coburn<sup>6</sup> have explained why this occurs in certain cases and offered suggestions for its prevention. They find the cause in the Arnold-Chiari malformation and the cure in a cerebellar and high cervical laminectomy, to be followed by repair of the spina bifida defect, no matter where its level. Other clinics, notably those in London, have used this same method. Their unpublished reports are favorable. The reference should be consulted for details. This malformation applies chiefly to those spina bifidas that have large sacs, even though in

\*Assistant professor of neurosurgery, Harvard Medical School; surgeon in chief, City Hospital.

these, as in all others, the degree of symptomatic peripheral recovery depends on the variety of tissue that has failed to fuse. Thus meningo- or encephalomyelocele has the least and the spina bifida occulta the most favorable outcome, regardless of the type of therapy.

#### INFECTION

**Infectious processes** that involve the central nervous system might be supposed to be outside the realm of neurosurgery. Nevertheless, it is true that because they frequently occur as complications of otherwise uninfected conditions, a knowledge of their characteristics is necessary for the neurosurgeon.

**Meningitis** Non-specific meningitis is still treated most successfully by as near an approach to constant lumbar drainage as is feasible, plus the administration of large amounts of fluid, preferably by mouth or, if that is not possible, by any other method. Constant lumbar drainage by either needles or indwelling ureteral catheters has not yet proved practical. Proved or suspected infections with *Streptococcus hemolyticus*,<sup>6</sup> the meningococcus,<sup>7</sup> the pneumococcus<sup>8</sup> and probably the influenza bacillus should be treated by sufficient sulfanilamide by mouth to insure promptly and to maintain constantly a 10 mg per cent or higher concentration of the drug in the blood at all times. Appropriate antiserums must also be used, and care taken to anticipate any toxic effect of the sulfanilamide by daily red and white blood-cell counts and the administration of sodium bicarbonate.

Meningitis following trauma is found, according to Courville and Platner,<sup>9</sup> to vary from 2.3 to 10 per cent in various series of autopsies, their figure being 6. The figures were collected from groups which ranged from 432 cases for the lowest figure to 1261 for their own. My<sup>10</sup> figures, as obtained from 1203 hospitalized patients, gave an incidence of 0.4 per cent. If only the fatalities were considered the incidence rose to 2 per cent. It seems justifiable to conclude that treatment accorded the patients in the series with the high incidences might have been susceptible of improvement.

**Brain abscess** This is a much-discussed problem so far as its treatment is concerned. I believe that the best evidence is to the effect that when the abscess is relatively young and heavily encapsulated, repeated tapping and inadequate drainage through a small rubber tube are equivalent to neglect. The preferred method should, if possible, be carried out in two stages. At the first stage, the bony opening is made, the abscess located and the meninges at the edge of the skull

defect sealed with the cautery or by an iodine-soaked pack. At the second stage, depending on its relation to the surface of the brain and its age, the abscess is opened and drained, marsupialized<sup>11</sup> or excised. Drainage is by means of loose packing with gauze around one or two rubber tubes,<sup>12, 13</sup> through a Mosher<sup>14</sup> copper-wire-gauze cone drain or by gauze pack alone, as described by King.<sup>15</sup> If the abscess is non-encapsulated or encephalitic in type, there is no method of treatment which approaches that of King<sup>16</sup> in efficiency or safety. Metastatic abscesses are usually considered to be multiple, but Courville<sup>17</sup> has made the statement that they are single in 50 per cent of the cases.

**Osteomyelitis of the skull** Although Adson<sup>18</sup> advocates only sequestrectomy and removal of all dead bone in osteomyelitis of the skull, the balance of opinion is against him. As emphasized by Hill,<sup>19</sup> the generally preferred method is to go farther than this and excise all dead bone through the adjoining viable edges, the excision to include not only the sequestra in the area but all other bone as well.

**Epidural spinal infections** Of these the commonest is epidural spinal abscess. According to the experience of Cohen<sup>19</sup> and others, the history of a sudden attack of acute excruciating pain in the back, followed by a rise in temperature and the onset of tingling, numbness and weakness in the legs with sensory and motor paralysis, together with bladder difficulties in the next few days or weeks, is typical. When a source for a septic metastasis and a cerebrospinal-fluid block at lumbar puncture can be demonstrated, or pus is found in the spinal epidural sac, laminectomy and surgical drainage are imperative and, in fact, often overdue. The prognosis improves directly with the promptness of operation and, with the aid of tidal drainage, may be good even in those cases in which the paralysis is already relatively far advanced.

#### INJURIES TO THE CENTRAL NERVOUS SYSTEM

**Craniocerebral injuries** With only rare exceptions, it is now generally agreed that the preferred treatment of the fundamental non-operable type of craniocerebral injury is by lumbar decompression combined with judicious dehydration. Subtemporal decompression is practically never indicated for its decompressive effect only, although exploratory trephination is well established as a diagnostic requirement.<sup>10</sup> Of the operable group, it is becoming increasingly evident that the subdural hematoma is much commoner than has been supposed and that the final diagnosis can only be made by means of exploratory trephination. It is therefore greatly to be regretted that Kaump and

## REPORT ON MEDICAL PROGRESS

## NEUROSURGERY

DONALD MUNRO, M.D.\*

BOSTON

TO RECORD progress in neurosurgery is to measure progress in medicine in general. Specialties are limited in name only, and then only because the specialist has sacrificed his general medical knowledge in favor of superknowledge about one single subject. With this superknowledge goes ignorance, and the specialist becomes a specialist not by virtue of what he knows but rather by virtue of what he knows he does not know. It is therefore the progress that is made in the fields outside, quite as much as the changes that take place within, that affect the advancement of a specialty. A discussion of the year-by-year alterations that have taken place within the field of neurosurgery cannot be a measure of progress but is rather a critique of methods and ideas.

CONGENITAL STATES AND THOSE ARISING  
AT OR JUST AFTER BIRTH

*Cyanosis of the newborn* In its neurological aspect the conception, now well established, that cyanosis within physiologic limits is the normal condition of the newborn, is second only in importance to the establishment of the fact that asphyxia, which is not cyanosis but pathologic anoxemia, is the fundamental factor in the determination of the degree of acute brain injury.<sup>1</sup> Treatment based on this concept determines, at the last analysis, the amount of future invalidism. If carried to its logical conclusion, it is apparent that lumbar decompression, supplemented by diagnostic subdural puncture and, if necessary, by temporal trephination and appropriate dehydration, is the only acceptable treatment for intracranial hemorrhage of the newborn. The possibility of an associated hemorrhagic diathesis is cared for by the routine intravenous administration of parental whole blood in any vein except the superior sagittal sinus.

*Porencephaly* This condition in which there occurs "a defect in the cerebral or cerebellar structure appearing as a cystlike cavity communicating with the ventricles or separated from them by only a thin layer of brain tissue, covered on the outside by the pia arachnoid and filled with a clear colorless fluid,"<sup>2</sup> may be the result of birth injury, is frequently associated with convulsive seizures

later in life and has commonly been regarded as not amenable to treatment from the point of view of relief of symptoms. My experience with 2 cases and Patten's<sup>2</sup> similar experience makes the outlook for these patients much more hopeful. There is no doubt but that in view of this evidence, anyone who is proved to have a porencephalic cyst should have a craniotomy and a destruction of the surface of the cyst cavity. The diagnosis is usually made by an encephalogram. Both examination and treatment should be instituted early in order to avoid the excessive cortical atrophy that otherwise develops.

*Communicating hydrocephalus* Dandy<sup>3</sup> has again drawn the attention of the medical public to Putnam's work in the treatment of communicating hydrocephalus. The latter's therapy called for destruction of the choroid plexus in the two lateral ventricles and possibly also in the lateral recesses of the fourth ventricle. It is the only method that offers any hope for these invalids, but too much should not be expected of it.

*Athetosis* Section of the extrapyramidal tracts in the spinal cord as a means of relieving athetosis<sup>4</sup> occupies a definite place in our armamentarium against this dreadful form of invalidism. While not yet curative, there is reason to hope that, with early diagnosis and treatment, more may be accomplished than mere relief of invalidism. The procedure is highly technical and should be undertaken only by one well trained in neurosurgery.

*Spina bifida* Although spina bifidas may be successfully closed, a well baby does not necessarily follow. A high percentage of these children develop an acute hydrocephalus which vitiates the surgeon's otherwise successful work. Penfield and Coburn<sup>5</sup> have explained why this occurs in certain cases and offered suggestions for its prevention. They find the cause in the Arnold-Chiari malformation and the cure in a cerebellar and high cervical laminectomy, to be followed by repair of the spina bifida defect, no matter where its level. Other clinics, notably those in London, have used this same method. Their unpublished reports are favorable. The reference should be consulted for details. This malformation applies chiefly to those spina bifidas that have large sacs, even though in

\*Assistant professor of neurosurgery, Harvard Medical School; surgeon in chief for neurological surgery, Boston City Hospital.

trephine holes on each side of the midline in the frontal bone as recommended by Cohn can be used when greater pull is desired and more particularly when the patient is able to stand the manipulation necessarily associated with their application. Plaster-of-Paris cuirasses in cervical cord injuries are contraindicated. This is not so when only the bony structures are involved. Castex casts,<sup>27</sup> if the expense can be borne and if they are properly applied, may prove to be a useful adjunct in the therapy of this condition in elderly people with a minimum (relative) of cervical cord injury. Extension of other parts of the abnormally flexed spinal column can, in the presence of associated cord injury, be carried out with safety to the patient during his recumbent period by placing a roll of blankets opposite the kyphos but beneath the mattress and on top of bed boards. The degree of extension can be varied by changing the size of the blanket-roll.

A further development in the problem of ruptured intervertebral disk has been introduced by Naffziger et al.<sup>28</sup> They report that thickening of the ligamentum flavum with pressure locally on and through the dura may occur alone or in association with a ruptured disk. The symptoms and diagnostic criteria are the same as those necessary to justify a laminectomy in search of an extruded nucleus pulposus.

#### TUMORS OF THE CENTRAL NERVOUS SYSTEM

*Intracranial tumors* Neurosurgeons have always recognized the need for some form of treatment other than surgery in dealing with certain of the more malignant and infiltrative types of brain tumor. Davis and Weil<sup>29</sup> report on the effect of both x-ray and radium therapy on intracranial gliomas and conclude that it is impossible to tell as yet what effect either method has. Frazier et al.<sup>30</sup> are somewhat more specific. In their experience they conclude that medulloblastomas are radio sensitive but are commonly under-radiated from the standpoint of quantity, that glioblastomas are little if at all affected by radiation, that certain astrocytomas are radio-sensitive especially in the group whose cells are not fully matured, that ependymomas showed marked radio sensitivity and that oligodendrogliomas are completely resistant to radiation. From the same clinic Carpenter et al.<sup>31</sup> write that attempts at the radical removal of tumors of the hypophyseal stalk carry an unjustifiably high mortality with no commensurate certainty of complete excision. They strongly advise repeated evacuation of the cystic portion and radiation of the solid remaining structure and assert that in this way intervals between necessary aspirations have been lengthened and

the rapidity of recurrence of symptoms slowed up. Carcinomatous metastases to the brain are usually considered to be inoperable once the diagnosis has been confirmed by histological examination of a biopsied specimen. This attitude arises out of the belief that the metastases are usually multiple. German,<sup>32</sup> however, in 14 cases of metastatic carcinoma of the brain found only 1 case with multiple tumors. In so far as it goes, this relation is significant, but as applied to the individual case, I doubt whether the many other conflicting factors justify paying undue attention to it.

Olivecrona<sup>33</sup> emphasizes the importance of radical surgery in the cellular types of cerebral vascular tumors. He points out, as others have, that these tumors are benign and usually favorably placed for excision. It should not be overlooked, however, that identification and therefore prognosis and the type of surgery depend on the histological identification of the tumor and that, conversely, diagnosis and therapy based on symptoms and signs that do not include this datum are worse than useless.

*Intraspinal tumors* Intraspinal tumors in children are not commonly diagnosed, usually because the possibility of the presence of such a condition early in life is not considered. Ingraham<sup>34</sup> emphasizes the obvious futility of such an attitude and by implication justifies the statement, which cannot be emphasized too strongly, that diagnosis at this age is no more difficult than that at any other time of life. Half his cases, as was to be expected, had tumors that arose from developmental cell inclusions, but a less predictable finding was the high percentage of meningiomas and rather advanced gliomas. Adson<sup>35</sup> summarizes the present-day knowledge in regard to intraspinal tumors in general. Again early diagnosis is of importance in regard to the outcome. The surgical mortality is low, —4 per cent, — and the prognosis hopeful, since 85 per cent of these tumors are benign. The one depressing part of the picture is found in the intramedullary varieties. Even with two-stage operations that permit auto-extrusion of the tumor after vertical section of the cord, and even in the face of a prolonged life expectancy, the relief of invalidism and restoration to economic self-support are not common in this group.

#### PERIPHERAL NERVOUS SYSTEM

*The brachial plexus* Neuritis of the brachial plexus which is mechanical in origin or, as more commonly phrased, the scalene syndrome has come to be recognized as an important cause of pain, atrophy, disability and circulatory changes in the

Love<sup>20</sup> should have seen fit to publish their fanciful theory about the formation of subdural hematomas. It is inexcusable at this time to publicize a revolutionary theory without overwhelming evidence in its favor and large experience to back it up. This is especially true when it is diametrically opposed to one that is already universally accepted and well established on abundant evidence. Their series of 13 cases of traumatic subdural hematomas, which has been stretched to 30 by the inclusion of syphilitics and patients with blood dyscrasias, is not enough to justify their conclusions.

The furor relative to the dangers of using hypertonic glucose solutions intravenously and to the corresponding necessity of substituting hypertonic sucrose solutions therefor has died, and glucose continues to be used. As has been recognized since the time of Aesculapius, "the study of mankind is man" and even with our modern facilities, conclusions based on animal experiments do not necessarily apply to the higher forms of life.

A study of craniocerebral injuries as seen among those students who participate in sports in a large university has been started.<sup>21</sup> So far, it has been demonstrated, at least in football players, that the question of water balance is the most important factor in the treatment of those who have received head injuries. Concussion<sup>10</sup> used in the self-limited pathological rather than in the loose lay sense is the usual lesion, with the prolongation of symptoms after recovery of consciousness being due to the associated toxic dehydration.

Puech and Krebs<sup>22</sup> make a valuable contribution to a better understanding of the post-traumatic syndrome. Their recognition of the frequency of the pocketing or laking of cerebrospinal fluid in thickened and scarred arachnoid tissue as a cause of so-called post-traumatic cerebral symptoms should go far toward helping to bring order out of the present chaos that afflicts this problem. Others have called attention to the similar importance of recognizing fluid subdural hematomas as another equally prolific organic source for these symptoms.

An unusual cause of traumatic cerebral edema is electric shock. It is important, however, because of its late effects and its relation to industry. As might be expected, the edema is associated with venous stasis, thrombosis, perivascular hemorrhages and cell death, with perivascular demyelination and incomplete necrosis. Alexander<sup>23</sup> in a well-documented paper produces evidence to show that electric shock causes cardiac inhibition which leads to anoxia and suffocation of the brain tissue. It may be tentatively concluded, in the light of analogous pathology in other forms of cranio-

cerebral injury, that the non-fatal cases can be expected to show varying degrees of interference with peripheral function. Industrial surgeons generally should not fail to consult this article.

*Injuries to the spinal cord* It is now well known that the first effect of an injury to the spinal cord is the production of spinal shock. Spinal shock throws out of gear, in a completely irregular fashion, all reflex activity below the level of the cord injury. The bladder, being fundamentally a reflex organ, is included in this disruption. Residual urine collects and becomes infected. The bacteria spread, involve the bladder, ureter and kidney and set up a major toxic infection, which in its turn brings back or continues the spinal shock with its changes. If untreated or treated by an indwelling catheter, no catheterization, intermittent credé of the bladder or suprapubic drainage, the incidence of infection in the genitourinary tract at the discharge of such patients from the hospital is 72 per cent. Treated by tidal drainage from the very start and with the infection limited to the bladder and rendered relatively innocuous because residual urine is not allowed to collect, the incidence of the same infection is only 14 per cent.<sup>24</sup> This difference is re-emphasized because a recent paper written by Sir J. Thomson-Walker<sup>25</sup> has resurrected the conclusions reached from a study of war wounds without the aid of and indeed before the development of tidal drainage. As applied to civil life, his conclusions are hardly significant in so far as the care and transportation of the wounded from the field to the base hospital goes, but his ideas relative to treatment instituted after the base hospital is reached may well be accepted as applicable to injured civilians if the reader has had no experience of his own to guide him. Attention is called to this article only to condemn the conclusions published therein as obsolete.

Surgical treatment of injuries of the spinal cord depends on the location of the cord damage and the presence or absence of a cerebrospinal fluid block. In cervical injuries, decompressive laminectomy—indicated under like circumstances in the lumbar and dorsal areas—is contraindicated even in the presence of a block. Traction, however, must be applied to the head. My experience leads me to believe that the most universally useful method is through a bridle which pulls from beneath the chin and occiput over an outrigger and which carries not more than 5 pounds of weight. The best of these are homemade of flannel bandage. Traction applied to the skull through tongs, the latest model of which is Barton's,<sup>26</sup> or by piano wire passed through adjoining

above. The article should be read by all interested in this problem. In particular, it should be pondered by those who find themselves intrigued by the thought that this disease can be treated by electrocoagulation of the gasserian ganglion, as proposed by Adler<sup>38</sup> from the Sauerbruch clinic. The latter reports 25 cases, with 1 fatal case due to either meningitis or air embolus, 2 cases of herpes zoster and 1 case with an enlarging ulcer of the ala nasi. The procedure is done without anesthesia through the foramen ovale and is said to spare the fibers of the first division. Mack<sup>40</sup> also recommends this procedure, although his series has only 23 cases and his ratio of complications is much higher than that of Adler. Kirschner states in the discussion of Mack's paper that electrocoagulation is now the method of choice in dealing with trigeminal neuralgia and cites 380 cases, with 87 per cent completely healed, however, these included a case of injury to the optic nerve and several cases of meningitis, and recurrence after three years occurred in 20 per cent. Grant's<sup>39</sup> comparative figures for the cases treated by incomplete section of the sensory root are 590 cases, with a recurrence rate of 7 per cent, 4 per cent of the cases had keratitis. In his larger series of 949 cases, the mortality was 1.36 per cent, meningitis having occurred twice.

*Ménière's syndrome* Ménière's disease or what may perhaps be spoken of as primary neuralgia of the vestibular nerve is still the subject of dispute in regard to therapy. Much of the confusion and most of the conflicting results that have arisen out of the various methods adopted to relieve the attacks of vertigo can be found in the failure to differentiate aural vertigo and Ménière's disease. The symptoms may be the same, but with aural vertigo the fundamental cause that initiates the attacks of explosive dizziness can be demonstrated. When this is corrected, the attacks usually cease. In this category fall the patients with foci of infection, with chronic ear disease and with collapse of the Eustachian tubes and those who suffer from dietary indiscretions and the like. Individuals who have similar vertiginous attacks but in whom it is impossible to demonstrate any known cause or in whom potential causes have been demonstrated and corrected without relief have Ménière's disease. Thus, as our knowledge of the cause of labyrinthitis or vestibular-nerve neuralgia increases, the number of patients with true Ménière's disease decreases and the number with aural vertigo increases. Most cases of aural vertigo can be relieved when the cause is corrected. No cases of true Ménière's disease can be relieved in this way because the cause is not demonstrable. Aural vertigo that still persists because the underlying cause

cannot be done away with is relieved by section of the vestibular nerve in about 8 out of 10 cases. The vertigo of Ménière's disease is relieved in every instance by section of the vestibular nerve on the side of the deafness and tinnitus, the tinnitus may be unaffected and the deafness either improves or remains as before. Temporary relief in many cases of true Ménière's disease can be obtained by the administration of potassium or ammonium chloride and the total elimination of sodium chloride from the diet. Potassium chloride is preferable and has a sounder basis for administration than has ammonium chloride. Permanent relief can be obtained by this treatment in a few of the same group of cases. The effect of this regime on aural vertigo is not known. In this connection, I have noted the occurrence of avitaminosis with the production of preclinical scurvy as the result of artificial limitation of diet. It led to a hemorrhage into the fallopian canal, with a peripheral facial palsy, that took place five days after section of the nerve. The paralysis cleared up completely in two weeks, coincidentally with the administration of large quantities of crystalline vitamin C.

In line with the attempt to demonstrate additional fundamental causes for Ménière's syndrome and thus to increase the group of aural vertigos, Hallpike and Cairns<sup>41</sup> have contributed a study of the histologic changes in the temporal bones of 2 of the former group of patients. They claim that the changes found are suggestive and are based on "a gross distention of the endolymph system together with degenerative changes in the sensory elements." The paper is important, because this is believed to be the first histological study that has ever been carried out in such patients. It should be noted, however, that the deaths occurred, and therefore the studies were made, one and three days respectively after the vestibular nerves had been divided.

#### CLINICAL ENTITIES

*Pain* Intractable pain, the cause of which cannot be corrected, lends itself to treatment by some form of denervation of the pain-bearing region. Hodgson<sup>42</sup> has reviewed the various methods at our disposal when the cause is cancer. They are chordotomy, section of the cranial nerves within the cranium, posterior rhizotomy, injection of peripheral nerves with alcohol and injection of alcohol into the spinal subarachnoid space. White<sup>43</sup> has suggested a useful modification of the standard method of carrying out the last procedure. By elevation of the hips to a higher level than that of the head and injection through the fourth lumbar space with the patient lying on his abdomen, he has demonstrated that the injected alcohol, be-

arm Naffziger and Grant<sup>36</sup> and Spurling and Bradford<sup>37</sup> have emphasized the variability of the symptoms, the fundamental causal background which is found in the relation between the shoulder girdle and the thoracic cage, the diagnostic significance of the effects produced by altering the position of the arm, and the lack of necessity of demonstrating the presence or absence of a cervical rib as one of the findings. On the other hand, all are agreed that the distortion of the brachial plexus by the interlaced or overlying scalenus anticus muscle is the significant factor in the production of the symptoms. Therapy based on this premise is successful and gives relief after varying periods of time from a few hours up to eight months. In the mild cases, it may be enough for the patient to practice exercises that strengthen the muscles which elevate the shoulder girdle, with perhaps additional mechanical support for the arm during the early stages. More severe cases must seek relief through surgery, however. In these latter, the muscle is cut away from its insertion into the first rib. The myotomy must be complete and must include all the muscle as well as its sheath. The muscle is usually hypertrophied and fibrosed and frequently has a sharp fibrous edge. If a cervical rib is present and is long enough to extend forward beneath the lower cord of the plexus, the rib must be excised. In view of the multiplicity of subjective symptoms and the paucity of objective signs, it is well to be sure that the scalene syndrome is not the cause of pain about the shoulder or in the arm, especially when, as Naffziger and Grant<sup>36</sup> put it "the signs all point to a peripheral neuritis of the brachial plexus with striking relation to posture." If this diagnosis can be made, relief through surgery will be striking. The possibility and, if the history warrants, the probability of a traumatic origin for an acute scalene syndrome cannot be denied.

In this connection, it is well to emphasize the inefficiency of operative therapy in the treatment of direct trauma to the brachial plexus. It is only rarely possible to suture any torn elements of the plexus with sufficient accuracy to get any greater degree of axonal regrowth than would develop without suture. This is particularly true if the tear is in the roots or the primary cords. On the other hand, if interruption is from a physiological rather than an anatomical cause, operative insult will only make bad matters worse. Compression by a supraclavicular hematoma, which is always associated with and often the chief cause of the interruption, is not corrected by the substitution of an operative scar for the lesion caused by the organization of the blood clot. On this basis, and because peripheral evidence of axonal

regeneration may not be demonstrable for six months after the injury, it is preferable to place the paralyzed arm in the modified Statue-of-Liberty position, with abduction at the shoulder, 90 degrees of flexion at the elbow and full supination of the hand, as soon after the injury as is possible, and to keep it there until the paralyzed muscles have been re-energized, or until six full months have passed without any evidence of decrease in the peripheral sensory or motor paralysis. While the supraclavicular hematoma is fresh, it should be treated by x-ray to diminish the amount and soften the tissue of the scar. During the period of splinting and afterward, the muscles must be maintained in a state of normal tone and size by constant massage, active and passive motion and electrical stimulation. Under this regime, it is scarcely ever necessary to interfere surgically with damaged brachial plexuses for the purpose of giving the patient the greatest possible amount of recovery from his disability.

#### CRANIAL NERVES

*Trigeminal neuralgia* In this country, the treatment of trigeminal neuralgia (tic douloureux) is either operative, with permanent relief, or by alcohol injection or inhalation of trichlorethylene, with temporary relief. The modern method of differential section of the sensory root by which the sensation and moisture of the cornea are kept intact has robbed the operation of practically all danger to the eye, and a better understanding of the danger of wide lifting of the basilar dura, with elimination of damage to the greater petrosal nerve and vein, has seconded that effect and in addition eliminated the postoperative facial paralysis. Furthermore, although the relief has been as widespread and permanent as with total section, the anesthetic area has been diminished in extent and the resultant disability largely done away with. An occasional case still is bothered with postoperative paresthesias, but this is less likely to occur if the operation is reserved for the cases with classical tic. The diagnosis is limited in this way to the individual who has attacks of pain interspersed with free intervals, who has the pain strictly limited to one side of the midline of the face and, above all, who can be shown to have a constant "trigger point," stimulation of which produces in every instance the typical attack and nothing else. The usual method of approach is still by way of the temporal fossa, and this in spite of Dandy's enthusiasm for the route through the posterior fossa. Grant<sup>38</sup> has reviewed 949 cases of this condition from the late Dr. Charles H. Frazier's clinic. Analysis of this group demonstrated essentially the data outlined

amenable to extensive diagnostic neurosurgical procedures previous to craniotomy or in which the neurologic signs are so widespread as to defy analysis, the study of the electroencephalographic tracings has given correct localizing information in a very high percentage. The technic still needs some refinement to make it more universally applicable, but the process is too important and helpful to justify depriving the patient and his surgeon of its aid on that account.

**Thorotrast** The use of Thorotrast as a diagnostic aid has been widely advocated in the European literature even to the absurd extreme of employing it in the neurological diagnosis of head injuries, as recommended by Loehr<sup>64</sup>. It is therefore refreshing to come upon a clear-reasoned paper dealing with the use of this radio-active substance from a rationalistic rather than a special-pleading point of view. In such an article, Stuck and Reeves<sup>65</sup> point out in no uncertain terms that the dangers attendant on its use are far too great to justify its continuance as a diagnostic agent. Those proposing to employ the material in this way should read the paper in detail and with due consideration for its contents. Additional reason against its universal use is found in its inaccuracy. Campbell, Alexander and Putnam<sup>61</sup> in their study of the vascular pattern in various lesions of the human central nervous system point out among other things that "the alterations of the vascular pattern in disease are non-specific reactions and are to a large measure independent of the etiology, they are similar in many conditions, such as primary vascular disease, trauma, inflammatory disease and poisoning."

#### ANESTHESIA

Unfortunately, some form of anesthesia is necessary if one is to do neurosurgery. By-effects, especially if bad, of usual anesthetics come properly within the review of the neurosurgeon. Although nitrous oxide is not commonly used in neurosurgery, no surgeon can afford to overlook the evidence accumulated during the year to the effect that inhalation of this gas may cause far-reaching and permanent major injury to the brain. Stewart<sup>38</sup> emphasizes the lethal effect of the associated asphyxia, and Courville<sup>57</sup> describes the pathologic changes found in the cerebral gray matter of patients who had been anesthetized by this method. O'Brien and Steegmann<sup>38</sup> also describe degeneration of the brain under the same circumstances. Cyclopropane has also been described<sup>59</sup> as the cause of postanesthetic encephalopathy. Idiosyncrasy to novocain has been frequently reported, but it occurs so rarely that the individual surgeon has little if any personal ex-

perience in the matter. Gilman's<sup>60</sup> paper on the treatment of dangerous reactions to this drug is timely. He describes three types of dangerous reactions. The first is an intoxication for which barbiturates are the antidote, being more effective in the form of sodium pentobarbital and when used as a prophylactic. The second type of reaction presents signs referable to collapse of the circulatory system with a variation from the mildest type, which is relieved by lowering the patient's head, to death from sudden circulatory failure. The difficulty in this group is thought to be due to inadvertent intravenous injection of the novocain solution. Treatment is unsatisfactory. The third type is allergic in nature, and the symptoms vary from a mild urticarial type of skin response, an example of which I have recently seen, to sudden death after injection of as small a quantity as 1 cc of a 2 per cent solution. No treatment is known, but the addition of adrenalin to the novocain solution, especially when large amounts are to be used in infiltration anesthesia, is undoubtedly a useful prophylactic procedure and one that should be adopted universally.

#### OPERATIVE TECHNIC

The importance of fluid metabolism and the extraordinary variations that may take place in the fluid balance of the body from causes that are usually either overlooked or ignored is emphasized in a paper by White et al<sup>63</sup> on the loss of blood during neurosurgical operations. They point out that this loss commonly reached figures that exceeded 1000 cc and which are dangerously close to the critical margin of 1200 cc, the loss of which will throw the patient into surgical shock. Even the smaller loss is tolerated only because it has leaked away slowly over a number of hours. When it is remembered that there is an additional loss of fluid from the skin and lungs, which in a neurosurgical procedure may reach another 1000 cc or more, it becomes apparent that preparations for the intravenous administration of fluids during operation and for blood transfusions at any time are essential in this kind of surgery.

cause of its specific gravity, floats to the highest point of the spinal subarachnoid space, in this case the region of the foramina of exit of the third to fifth sacral nerves. Because of the position, the effect is exerted bilaterally, and peripheral anesthesia and hypesthesia is complete and widespread. He advocates it as a substitute for chordotomy in poor-risk patients whose life expectancy is short and advises that the patient be prepared to face constant drainage of the urinary bladder, provided that he has not been already condemned to this arrangement.

Pain in the face provides one of the most difficult fields for diagnosis and treatment. This is particularly true when the type, distribution and historical sequences of the development of the pain do not conform to typical groupings of disease. Atypical pain has been shown to be due to malocclusion of the jaws, enlarged nasal turbinates, functional abnormalities of the sympathetic nervous system and numerous other causes. Glaser and Beerman<sup>62</sup> have analyzed 200 such cases in a well-documented article. They call attention to the often overlooked points that atypical facial pain is constant and not intermittent like true trigeminal neuralgia, that it is usually felt in the area supplied by the facial or external maxillary artery, that it is usually described as deep-seated, burning and throbbing, that women are affected three times more often than are men and that sympathetic phenomena are present in half the cases. Atypical facial neuralgia must be differentiated from trigeminal, glossopharyngeal and superior laryngeal neuralgias, all of which are paroxysmal in type.

While not strictly a surgical procedure, attention should be called to the use of snake venom as an analgesic in those patients whose pain would otherwise force surgery upon them. Macht<sup>44</sup> has reported 70 per cent of good results in the treatment of patients with various painful conditions. He used cobra venom. More limited experience with the same material in the Neurological Unit of the Boston City Hospital tends to confirm his results. The venom comes in ampules, and ten of them constitute one course of treatment.

*High blood pressure* Investigation in the rationale and efficiency of surgical treatment for essential vascular hypertension waxes apace. One can find support for almost any claim, either pro or con, in the flood of papers that have swamped the surgical literature in the past year. Good summaries with perhaps a slight surgical bias have been published by Davis and Barker<sup>45</sup> and by Martin.<sup>46</sup> Leriche<sup>47</sup> may be said to represent the foreign point of view and Page<sup>48</sup> the medical aspects. The best fundamental work is undoubtedly

that done by Heymans.<sup>49, 50</sup> There seems to be a general agreement that in a patient who has a labile blood pressure which is high while active and which falls when he remains in bed and who has symptoms severe enough to make him willing to undergo a major surgical procedure with no assurance that it will give him relief, any one of several operations will give a high percentage of symptomatic cure for an unknown time. As a sidelight on this, there can be no doubt but that the definition of what constitutes normal blood pressure and essential and malignant hypertension is a purely individual one with its maker. Furthermore, there are almost as many surgical methods of attack as there are schools of attackers while, at the same time, there is a dearth of adequate long-time follow-up on cases, no matter how treated. In short, it appears that the surgery of essential or malignant hypertension rests today on the questionable groundwork of confused diagnostic criteria, a multiplicity of methods, inadequate observation, and significant success only in mild cases. Such surgery can only be described as experimental, and patients should be operated on only with that understanding.

*Carotid-sinus syndrome* The occurrence of certain sudden fainting attacks in patients who are otherwise well has been found to be due to an abnormal response on the part of one of the carotid sinuses. The onset of the attack can often be traced to pressure over the bifurcation of the artery. This may have been produced by turning the head, by the pressure of the pillow or an arm against the neck during sleep, the wearing of a tight collar, and the like. Most of these attacks can be controlled by the administration of appropriate drugs. There is, however, a small residue that have to have surgery. The surgery takes the form of excision of the offending sinus and its nerves by denervating the carotid bifurcation and the adjoining 2 or 3 cm. of the three arteries that make it up. Failure to recognize the diagnostic and therapeutic possibilities of this condition has obvious implications. In line with this general problem, Heymans<sup>51</sup> has considered the more fundamental aspects of the condition and Robinson<sup>52</sup> has suggested that amphetamine (Benzedrine) sulfate may be of use as an adjunct to ephedrine in the non-surgical depressor type of hyperactive carotid-sinus reflex.

#### DIAGNOSIS

*Electrotechnic* Although mentioned in last year's review, the importance of electroencephalograms as diagnostic aids in the localization of brain tumors justifies citing again the work of Williams and Gibbs.<sup>53</sup> In cases that for various reasons are not

## CASE 25091

## PRESENTATION OF CASE

An eleven-year-old girl was admitted complaining of nervousness, headaches, vomiting and convulsions.

The patient was well and active, though inclined to be nervous, until one year prior to entry when almost daily attacks of headache began. These were moderately severe, always located in, behind or just about the right eye. They were occasionally associated with vomiting, but usually disappeared quickly, never interrupting play for more than five minutes. A gradual loss of weight began simultaneously with the onset of the headaches. Nine months before entry, while rollerskating, she had had a very severe right frontal headache accompanied by "pain in the stomach" and vomiting. She was put to bed, but the headache continued, preventing sleep. On the fourth day an "attack" ensued, the arms becoming flexed and the legs extended, without twitchings, convulsions or incontinence. She was conscious, talked normally and cried during the attack. Her physician sent her to an outside hospital where the attack was said to have stopped after a half hour.

Physical examination then showed a sallow, undernourished girl, apparently quite ill, complaining of severe frontal headache. The right biceps reflex was weak, the left, absent. The abdominal and leg reflexes were equal and active. There was no clonus, and no plantar response. A Mantoux test was slightly positive, but an x-ray film of the chest was negative. After two weeks in the hospital, having received "little white pills," ice packs and a diet which caused her to gain weight, she returned to school.

Her headaches continued to occur five or six times weekly, and she vomited three or four times weekly, though her appetite was good and her weight remained stationary. She became increasingly nervous, and her color at times seemed somewhat yellow and dark. The urine and stools remained normal. Eight days before admission the patient lay on a sofa, complained of headache and stated that she could not see, she then talked irrationally and recognized no one. Again she became stiffened and paralyzed, staring straight ahead.

There were no convulsive movements or incontinence. The attack lasted half an hour, following which she regained consciousness but was drowsy. She slept most of the succeeding three days, although she could be aroused. During the four days before entry she was very weak, staggered from side to side and vomited about once daily. During the year she had had urinary frequency, urgency and nocturia two to three times weekly. She was the ninth of twelve children, but her siblings were living and well. Her birth was normal, as was her postnatal development. Her father had typical migraine headaches, which were hemicranial and associated with nausea and vomiting.

Physical examination showed a well-oriented, intelligent, thin girl. The skin appeared tanned. A downy lanugo type of hair was present over the lower neck and spine. There was no breast development, but the genitalia were well developed and the pubic hair appeared normal. The general physical examination was negative. The blood pressure was 96 systolic, 70 diastolic. Neurological examination showed the eye muscles to be normal. The fundi showed obliteration of the disk margins, with three diopters of choking on the left, two on the right. There were flame-shaped hemorrhages along the nasal border of the left disk. Vision was 20/20 bilaterally with the patient's glasses. The visual fields were normal except for slight enlargement of the blind spots. There was minimal rotary nystagmus on looking to the right. The gait was slightly unsteady, with staggering on turning quickly. There was very slight swaying in the Romberg position. There was slight asynergy on the finger-to-nose test. The deep reflexes were essentially normal except that the knee jerks were slightly more active on the right on one examination. The Babinski was negative on the right, on the left it was equivocal on one occasion, positive on another, negative on another. Sensory examination was negative.

The temperature was 98°F, the pulse 58, and the respirations 19.

Examination of the urine showed a specific gravity of 1.020 and epithelial cells, debris and an occasional pus cell in the sediment. The blood showed a red-cell count of 4,500,000, 100 per cent hemoglobin, and a white-cell count of 10,500 with 60 per cent polymorphonuclears. A blood Hinton test was negative. A 1:1000 tuberculin test was negative. An electroencephalogram showed slow waves on all leads but indicated a definite focus in the right frontal area. The findings were consistent with a deep lesion causing increased intracranial pressure and hydrocephalus although

ventricles, and headache By pressure or invasion of the pituitary gland and hypothalamus, endocrine and vegetative functions could be altered I see nothing in the history or examination to suggest a lesion in the frontal, parietal, temporal or occipital lobes

The results of the air studies, both by ventricular and lumbar routes, may be summarized as indicating a block in fluid passage from the lateral ventricles, with their consequent dilatation It is suggested that a mass occupies the region of the third ventricle and also obstructs the basal cisternae That this tumor did not take origin within the third ventricle is proved by the lack of separation or of deformation of the lateral ventricles

We must therefore come to the conclusion that a tumor of considerable size occupies the territory above the sella displacing or invading the third ventricle Such suprasellar tumors occur in children, as in adults, and, although rare, are apt to fall into the group of craniopharyngiomas

DR JAMES R LINGLEY The plain films show increased convolutional markings, and the sella turcica, although it is not enlarged, is deformed The clinoids are pushed downward, and the sella is flattened The anterior clinoids are sharpened, and the posterior ones are markedly eroded However, the signs in the sella can be secondary to pressure, the result of tumor anywhere in the skull The pineal body is very finely calcified, and by measurement it was slightly posterior to its normal position Usually that means a tumor anterior to the pineal body In the ventriculogram, the lateral ventricles, as you see, are markedly dilated and there is complete absence of air in the third ventricle, indicating a block distal to the foramen of Monro After lumbar injection of air you can see air in the cervical canal. It passes anterior to the pons, fills the posterior portion of the cisterna interpeduncularis and then stops There is a block at the posterior margin of the sella We were hoping that the air by the lumbar route would enter the fourth ventricle and definitely rule out tumor below the tentorium The fact that it did not fill is not very good evidence in favor of a cerebellar tumor, however, as it occasionally does not fill in the normal person

DR AYER Was there an anteroposterior view to show dislocation of the ventricle? I assumed there was not

DR LINGLEY It shows marked symmetrical dilatation of the lateral ventricles, without deformity, and absence of filling of the third ventricle

DR TRACY B MALLORY Would anyone like to criticize or disagree with Dr Ayer's diagnosis?

DR PHILIP S BUCKLEY I should like to be a

little bolder and suggest an even rarer lesion—a colloid cyst of the third ventricle. The absence of separation of the lateral ventricles may be against this, but the history is suggestive We have a year's history of intermittent daily headaches of short duration, strongly suggesting an intermittent cause such as a pedunculated tumor This is supported by the normal visual acuity which shows that papilledema was of recent development If we suppose the tumor originated rather to the right side we could explain the fact that the early headaches were largely right-sided

DR AYER I considered that, but this x-ray film which we have seen showing no evidence of separation of the lateral ventricles is strong evidence against it.

DR GILBERT HORRAN Do you think the ventricle would be obliterated by a colloid cyst? They are usually small

DR AYER I should expect to see some of the third ventricle

DR HORRAN Usually in cases with these colloid cysts you see a little bit of ventricle starting in the foramen of Monro, I do not see any here.

#### CLINICAL DIAGNOSES

Brain tumor, <sup>?</sup> suprasellar cyst  
Hydrocephalus

#### DR AYER'S DIAGNOSIS

Suprasellar tumor, probably craniopharyngioma

#### ANATOMICAL DIAGNOSES

Polar spongioblastoma of third ventricle  
Congenital anomalies absence of left ureter and kidney, rudimentary cervix and vagina, absent uterus

#### PATHOLOGICAL DISCUSSION

DR CHARLES S KUBIK The tumor is just where Dr Ayer thought it would be It is a large mass, measuring 7 by 5 by 3.5 cm., occupying the space between the optic chiasm and cerebral peduncles and extending upward and completely filling the greatly dilated third ventricle Microscopically the tumor has a loose structure and contains extensive accumulations of colloid like material, probably a product of degeneration The cells are fusiform and of uniform size, with scanty cytoplasm and elongated, rather slender nuclei Some of the polar processes seem to have fibrillar prolongations The tumor, which I should classify as a polar spongioblastoma, is almost identical, grossly and histologically, with two others previously observed at this hospital\* There were

One of these has been previously discussed (Case 21,52) Case histories of the Massachusetts General Hospital. New Eng J Med 212:1181-1184 1935

the exact location could not be determined. X-ray films of the skull showed increased convolucional markings and a long, shallow sella.

On the fourth hospital day the patient vomited a small amount of material, after which the blood pressure rose to 120 systolic, 98 diastolic. She had a frontal headache and could not sleep. One half hour later the blood pressure was 105 systolic, 80 diastolic, and the pulse 72, she felt better and went to sleep. Two days later there were no abnormal findings except choked disks. On the eighth hospital day a ventriculogram was done, which yielded a very large amount of fluid from both ventricles and showed free communication. The films showed grossly dilated lateral ventricles which were symmetrical and not displaced or otherwise deformed. There was no filling of the third and fourth ventricles or aqueduct. Air was then injected through the lumbar route and passed into the cisterna magna and forward into the upper limits of the cisterna pontis, but it did not enter the cisterna interpeduncularis or chiasmatica. It also failed to enter the fourth ventricle. The pineal gland was at the posterior limit of normal. The ventricular fluid showed 2 lymphocytes and 24 red cells per cubic millimeter and a total protein of 10 mg per cent.

Following the air injection, the patient's condition suddenly became critical. Respirations were irregular, and the patient cyanotic. The right ventricle was tapped, air gushing out under great pressure. The first part of the fluid removed was pink, later becoming grossly bloody. Fifteen minutes later the left ventricle was tapped, yielding bloody fluid. Following this her ventricles were tapped every four hours. On the ninth hospital day she again became cyanotic, respirations ceased, and the pulse could not be felt at the wrists. The right ventricle was tapped, revealing grossly bloody fluid. Artificial respiration was started and maintained for eight minutes, when the patient gasped and began breathing spontaneously. Her condition remained critical, the temperature falling to 95°F and the pulse rising to around 200. On the tenth day the temperature rose sharply to 104°F, the pulse remained at about 200, the respirations rose to 60 and she died shortly afterward.

#### DIFFERENTIAL DIAGNOSIS

DR JAMES B AYER. A girl of eleven years, of normal birth, with eleven healthy siblings, is well until one year before admission. For three months she has daily attacks of headache located behind the right eye, associated occasionally with vomiting. The attacks are brief and do not interfere with play. As her father suffered from migraine it was probably thought that the patient was sim-

ilarly affected. Not until she has an exceptionally long attack of headache and vomiting, accompanied on the fourth day by stiffening of all limbs, do we feel that something serious is afoot. It is noteworthy that the "attack" of stiffening was not accompanied by convulsions or loss of consciousness. It recalls somewhat the picture of decerebrate rigidity. An examination at this time fails to show any definite cause for her symptoms, although progressive intracranial disease must be suspected. The course of illness continues about as before until eight days before entry to the hospital when a seizure similar to the last in respect to stiffening of the limbs occurs. But this attack is accompanied by temporary blindness and unconsciousness. It is now obvious that intracranial mischief must be considered as quite certain.

Her physical status appears to be quite normal, although the patient had lost weight, and endocrinopathy is perhaps suggested by the development of the genitalia, the persistence of lanugo hair and the yellowish cast to the skin. The usual laboratory tests must be considered as negative. The mental status is said to be normal. Neurologically the examination shows at times nothing but choked disks with hemorrhage, at other times slight unsteadiness in use of the arms and legs and reflexes which are asymmetrical and variable but rarely abnormal. Apparently no abnormality of cranial-nerve function was found, except minimal nystagmus. The presence of choked disks confirms our suspicion that we are dealing with increased intracranial pressure, and the presence of convolucional markings by x-ray further strengthens this belief. But as yet we cannot say whether the pressure is due to fluid (hydrocephalus) or an expanding lesion or both.

While the course of this illness strongly suggests the progressive course of tumor, I see no symptoms or signs which can definitely localize it. Sudden accessions of headache and vomiting, here so conspicuous as a feature, frequently indicate hydrocephalus, and in children especially, we look for the cause in obliteration of the fourth ventricle or aqueduct by tumors in the cerebellum or brain stem. The paucity, at times the absence, of cerebellar and cranial-nerve signs is here strong evidence against an expanding lesion below the tentorium. Obliteration of the aqueduct by ependymitis must be admitted as a possibility, and intermittent occlusion of fluid communication in the third ventricle is not at all uncommon. A tumor in the latter region may also cause spasm in the extremities by pressure on the crura and, if large enough, may cause blindness by compression of the visual tracts. Such a tumor would unquestionably lead to internal hydrocephalus of the lateral

ventricles, and headache By pressure or invasion of the pituitary gland and hypothalamus, endocrine and vegetative functions could be altered I see nothing in the history or examination to suggest a lesion in the frontal, parietal, temporal or occipital lobes

The results of the air studies, both by ventricular and lumbar routes, may be summarized as indicating a block in fluid passage from the lateral ventricles, with their consequent dilatation It is suggested that a mass occupies the region of the third ventricle and also obstructs the basal cisternae That this tumor did not take origin within the third ventricle is proved by the lack of separation or of deformation of the lateral ventricles

We must therefore come to the conclusion that a tumor of considerable size occupies the territory above the sella displacing or invading the third ventricle Such suprasellar tumors occur in children, as in adults, and, although rare, are apt to fall into the group of craniopharyngiomas

DR. JAMES R. LINGLEY The plain films show increased convolucional markings, and the sella turcica, although it is not enlarged, is deformed The clinoids are pushed downward, and the sella is flattened The anterior clinoids are sharpened, and the posterior ones are markedly eroded However, the signs in the sella can be secondary to pressure, the result of tumor anywhere in the skull The pineal body is very finely calcified, and by measurement it was slightly posterior to its normal position Usually that means a tumor anterior to the pineal body In the ventriculogram, the lateral ventricles, as you see, are markedly dilated and there is complete absence of air in the third ventricle, indicating a block distal to the foramen of Monro After lumbar injection of air you can see air in the cervical canal It passes anterior to the pons, fills the posterior portion of the cisterna interpeduncularis and then stops There is a block at the posterior margin of the sella We were hoping that the air by the lumbar route would enter the fourth ventricle and definitely rule out tumor below the tentorium The fact that it did not fill is not very good evidence in favor of a cerebellar tumor, however, as it occasionally does not fill in the normal person

DR. AYER Was there an anteroposterior view to show dislocation of the ventricle? I assumed there was not

DR. LINGLEY It shows marked symmetrical dilatation of the lateral ventricles, without deformity, and absence of filling of the third ventricle

DR. TRACY B. MALLORY Would anyone like to criticize or disagree with Dr. Ayer's diagnosis?

DR. PHILIP S. BUCKLEY I should like to be a

little bolder and suggest an even rarer lesion—a colloid cyst of the third ventricle. The absence of separation of the lateral ventricles may be against this, but the history is suggestive We have a year's history of intermittent daily headaches of short duration, strongly suggesting an intermittent cause such as a pedunculated tumor This is supported by the normal visual acuity which shows that papilledema was of recent development If we suppose the tumor originated rather to the right side we could explain the fact that the early headaches were largely right-sided

DR. AYER I considered that, but this x-ray film which we have seen showing no evidence of separation of the lateral ventricles is strong evidence against it

DR. GILBERT HORRAN Do you think the ventricle would be obliterated by a colloid cyst? They are usually small

DR. AYER I should expect to see some of the third ventricle.

DR. HORRAN Usually in cases with these colloid cysts you see a little bit of ventricle starting in the foramen of Monro, I do not see any here

#### CLINICAL DIAGNOSES

Brain tumor, ? suprasellar cyst  
Hydrocephalus

#### DR. AYER'S DIAGNOSIS

Suprasellar tumor, probably craniopharyngioma

#### ANATOMICAL DIAGNOSES

Polar spongioblastoma of third ventricle  
Congenital anomalies absence of left ureter and kidney, rudimentary cervix and vagina, absent uterus

#### PATHOLOGICAL DISCUSSION

DR. CHARLES S. KUBIK The tumor is just where Dr. Ayer thought it would be It is a large mass, measuring 7 by 5 by 3.5 cm., occupying the space between the optic chiasm and cerebral peduncles and extending upward and completely filling the greatly dilated third ventricle Microscopically the tumor has a loose structure and contains extensive accumulations of colloid-like material, probably a product of degeneration The cells are fusiform and of uniform size, with scanty cytoplasm and elongated, rather slender nuclei Some of the polar processes seem to have fibrillar prolongations The tumor, which I should classify as a polar spongioblastoma, is almost identical, grossly and histologically, with two others previously observed at this hospital\* There were

\*One of these has been previously discussed (Case 21757). Case histories of the Massachusetts General Hospital. New Eng. J. Med. 212:1181-1184, 1935.

three small implantations on the roots of the cauda equina

DR. MALLORY There were a few surprising findings in the remainder of the autopsy that had little to do with the clinical course. The genitourinary tract was very abnormal. At the apex of the vagina was a small nubbin 8 mm in diameter which appeared to represent the cervix. There was no uterus above it, however. One kidney and one ureter were entirely missing. On the same side there was a perfectly good tube and ovary. On the other side no tube was found but an elongated cord which had no lumen. It ran out into the sigmoid mesentery and at its end was a fusiform structure which contained a small amount of ovarian tissue.

### CASE 25092

#### PRESENTATION OF CASE

A twenty-eight-year-old, Irish-American man entered complaining of abdominal swelling and constipation.

For one and a half years preceding entry the patient had occasional attacks of epigastric discomfort appearing approximately half an hour after meals and relieved by soda. They did not follow every meal. He believed that they were due to the ingestion of catsup. Two weeks prior to entry, after a day of heavy lifting, he noted a feeling of fullness in his lower abdomen. The following day he felt distinctly under par and noted that his abdomen was sore to touch below the umbilicus, especially on the right side. He went to work the next day and noted distention of the lower abdomen on returning home that evening. Since he had been constipated for three days he had recourse to an enema, which resulted in the passage of gas but no feces. The following day, three days after onset, he remained at home and was given three "high enemas," which produced only gas. On the same day he took an entire bottle of citrate of magnesia, which caused the passage of a moderate amount of hard, dark feces and a large amount of gas. Following this the distention and soreness were much relieved and he felt better. He took "laxatives" twice daily after this and had a bowel movement once a day. On the sixth day before entry he stopped taking laxatives and returned to work. He had no bowel movement until two days before admission, following a large dose of laxative. In spite of the bowel movement his general malaise, lower abdominal distention and soreness in the right lower quadrant returned. Nausea and vomiting did not occur at any time during his illness. His symptoms became progressively worse, although

he slept well on the second night before entry. He took laxatives several times, and each dose was followed by the passage of small amounts of hard dark-colored stools and much gas. During the night preceding the day of entry his symptoms caused him to sleep very poorly, although he felt better in the morning. He was persuaded by his family and friends to come to the hospital for a "checkup." During the two days before entry he had taken nothing by mouth except fruit juices and water. Previously his appetite had been normal and he had been eating the usual types of food. His bowels had been regular and normal in appearance until the onset of his present illness. He had not lost weight. His past and family histories were noncontributory.

Physical examination revealed a well-developed and nourished man, not acutely ill. The head and chest examinations were negative. The blood pressure was 110 systolic, 74 diastolic. The abdomen was somewhat distended and tympanic. There was some spasm on the right, most marked over McBurney's point. The right lower quadrant was dull to percussion, and there was tenderness over a 5 cm area at McBurney's point. A 5 by 3 cm mass seemed to be present in the right lower quadrant but was palpated with difficulty because of the spastic abdominal wall. There was no indirect tenderness. Rectal examination was negative. Examination of the stools showed a 4+ guaiac test on the day of admission and negative tests on the second and fifth hospital days.

The temperature was 100.4°F, the pulse 96, and the respirations 24.

Urine examination was negative. The blood examination showed a red-cell count of 4,000,000 with 75 per cent hemoglobin, and a white-cell count of 17,000 with 85 per cent polymorphonuclears, 3 per cent large lymphocytes, 10 per cent small lymphocytes, 1 per cent monocytes and 1 per cent eosinophils. The nonprotein nitrogen of the serum was 26 mg, the serum protein 6.8 gm and the carbon dioxide combining power 65 l vol per cent. The chlorides were equivalent to 99 cc of N/10 sodium chloride. A blood Hinton test was negative.

A barium enema flowed without delay to a point in the transverse colon opposite the spine, where it stopped. After amyl nitrite had been administered, the barium was seen to trickle through a small opening about 5 mm in diameter. The constriction measured about 8 cm in length, and the mucosal pattern was entirely destroyed. Beyond this the hepatic flexure and ascending colon filled well. The cecum had a filling defect on its medial margin, which corresponded to the lat-

eral margin of the tumor palpated in this area. The terminal ileum filled and had a similar pressure defect from the tumor. The tumor was the size of a large grapefruit.

On the seventh hospital day an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR JAMES E. FISH. First of all we note some epigastric trouble that he had had for a year and a half, which, while inconclusive, is somewhat suggestive of ulcer. I think that we can consider it more or less irrelevant so far as the present difficulty is concerned. At least that is the hypothesis with which I must start.

Fourteen days before admission he had the first of a new series of symptoms, and I think one always should attach a great deal of importance to the first symptom. This was fullness in the abdomen. It was not pain in the abdomen or vomiting—simply fullness. On the thirteenth day before admission he had some soreness in the right lower quadrant, which came on after the fullness. On the twelfth day he was more distended, but we still have not heard particularly about pain, just distention. He took three enemas and a bottle of magnesium citrate, which is a moderately good dose of salts, and passed a large amount of gas and hard feces. Then he was considerably relieved. On the eleventh, tenth, ninth, eighth and seventh days before admission he appears to have stayed home, taking various sorts of laxatives, and on the sixth day felt enough better to go back to work. Up to this time the only clue we have is that of obstruction. For three days after returning to work he had no bowel movements, and toward the end of that period he again began to notice discomfort in the right lower quadrant and distention. On the second day before admission he was feeling considerably worse. He was more distended and he had more soreness in the right lower quadrant than he formerly had had. It is interesting to note that he had no nausea or vomiting. Assuming that he had an obstruction low in the large bowel, one might readily understand the absence of vomiting, but I think it is rather unusual not to have had some degree of nausea. Possibly he had more than is indicated by the story, since he declined food except fruit juices and water. This onset should not be spoken of as sudden. It was not a fulminating sort of obstruction, and yet it was rather abrupt. We have the impression from the history that over a considerable period of time he had no change in bowel habits. They had been practically normal, without change,—and that is significant,—right up until two weeks

before admission. Furthermore, we get the story that he had not lost weight. This seems to be considerable evidence against obstruction due to carcinoma. To what then is his obstruction due?

From his physical examination we find that he had tenderness and spasm in the region of McBurney's point, and a small mass 5 by 3 cm in diameter was felt. This tender mass would lead us to believe that the trouble probably was inflammatory. We have corroborative evidence of an inflammatory process in the temperature, which was 100.4°F and in a white count of 17,000. With an inflammatory mass in the region of the cecum it is surprising that he did not have any rectal tenderness. We then learn that guaiac tests on his stools were very inconstant. On one occasion he had a strongly positive test, and on two other occasions there was no blood. The hard, dark feces passed at home may have contained blood, it is not at all certain, however. I do not believe we can attach any special significance to them. He did not appear to be acutely ill at the time of admission, so that if he had obstruction it must have been partial, intermittent or low down.

From the laboratory work we are not able to gather very much that really helps us. He had a slight degree of anemia, a rather pronounced polymorphonuclear reaction and a total white count of 17,000. We note that he had 13 per cent lymphocytes and only 1 per cent monocytes, which is a ratio of 13:1, sometimes said to be suggestive of tuberculosis. The nonprotein nitrogen, the sodium chloride, the carbon-dioxide combining power and the serum protein were all within normal limits. The most we can say at this point is that the man appeared to have rather low obstruction, plus evidence of an inflammatory process, either primary or secondary to the mechanical obstruction.

The x-ray evidence ought to be very helpful. Instead it is confusing. The barium enema flowed to a point in the transverse colon opposite the spine, where it stopped. On physical examination on admission no mention was made of any mass or tumor in the region of the transverse colon. The mass described was at McBurney's point. Then on further interpretation of the films we learn that with amyl nitrite, presumably not before but after it was administered, barium was seen to trickle through a 5-mm lumen. That is a very small opening. Since the barium did not go through the opening before but did so after the administration of amyl nitrite, it leads one to suppose that there was some element of spasm as a cause of this obstructing lesion. Then we read farther on that the constriction was 8 cm in length, considering the extreme smallness of the lumen, this is

rather long I do not believe that is at all consistent with carcinoma of the transverse colon, in the absence of symptoms of more than two weeks' duration. I am somewhat puzzled by the fact that the mucosal pattern was entirely destroyed. That would lead us to believe that there was an intrinsic lesion in the bowel, which might be a carcinoma. An extrinsic lesion or pressure should not wipe out the pattern. I have been toying with the thought that this was a rather intermittent type of obstruction, very severe at one moment and letting up at another, over a period of two weeks. He might conceivably have had an intussusception, even though it is a rare lesion in adults.

Reading farther on, we get information about the mass in the region of the cecum and we find that it was on the medial side of the cecum, in the area between the terminal ileum and the cecum, and instead of being 3 by 5 cm it was about the size of a grapefruit. In other words, it grew from 5 to 15 cm in the week in the hospital. This could hardly be consistent with anything except an abscess. I am entirely at a loss to know whether we are dealing with two tumor masses or one confluent mass. It is possible that the obstructing mass in the transverse colon which the x-ray man picked up was not present at the time of admission to the hospital. It may have been more or less intermittent in nature, but the tumor mass in the region of the cecum was more constant and was undoubtedly an abscess.

DR. AUBREY O. HAMPTON: I might say that these films are about as confusing to me as they are to Dr. Fish, particularly after reading the history. In the first plain film he did have evidence of small-bowel obstruction and no evidence of colonic obstruction. The ileum was dilated and filled with gas at that time. In this film, taken one day later, the cecum and ascending colon are dilated, but with the barium enema, and these loops of small bowel are still filled with gas. The soft-tissue mass, which seemed to be demonstrated very well after barium, is not seen in the plain film, there is diffuse density in the right lower quadrant, which seems to press the cecum up and backward a little. The tip of the cecum is at the crest of the ilium, so if we were to select the center of the mass after the barium enema we would place it at a point midway between the transverse colon, which is at the upper margin, and the tip of the cecum, which is at the lower margin, or about at McBurney's point. Then after studying the mucosa and the defect in the transverse colon we are almost forced to the conclusion that the mass involved the mucosa of the transverse colon. This is at least so in one or two of the films. You get the impression that the de-

fect in the colon changes in shape, particularly here. It is smooth and conical at one extremity and markedly irregular at the other, although it does look as if it had changed in size and shape. Amyl nitrite also changes it, so we might assume that instead of the mucosal pattern's being destroyed we are not able to demonstrate it because of contraction of the colon. I think it is true that at times we are unable to demonstrate the mucosa when it is involved by extrinsic disease, because the musculature is so contracted that we cannot spread it out by pressure in normal fashion. We injected air, a double contrast enema, which shows a picture quite consistent with carcinoma. The defect has again changed somewhat. This time it appears to resemble a carcinoma of the transverse colon, but the lesion of the colon is not in the center of the mass, it is at the upper margin.

DR. FISH: Where is the lesion that is 8 cm long?

DR. HAMPTON: From here to here in the transverse colon. The ileum, strangely enough, crosses the center of the mass and is perfectly normal at this time except for displacement.

DR. FISH: You would not say there was spasm in the ascending colon?

DR. HAMPTON: The cecum is contracted slightly but the ascending colon is not.

DR. FISH: The ascending colon appears free from intrinsic disease?

DR. HAMPTON: Yes, the only thing wrong is dilatation.

DR. FISH: I did not visualize a low transverse colon with a mass as far toward the right as this is. I think in view of the x-ray picture it is perfectly logical to conclude that the whole process is limited to one tumor mass. It would seem now that intussusception was an idle, passing thought. It is conceivable that the degree of obstruction might be intermittently aggravated somewhat by spasm and extrinsic pressure. At least we have to think of some manner in which this man with an opening in his bowel of only 5 mm was able to get along without completely blowing up. It is possible that the inflammatory mass near the cecum represents perforation of an otherwise normal cecum, due to back pressure from obstruction lower down in the transverse colon, thereby producing the abscess mass. We certainly cannot rule out the possibility of carcinoma in the transverse colon, in view of what Dr. Hampton has said, and we have to account for a tender inflammatory mass which may have occurred in the way I have just mentioned or may have resulted from infection burrowing through the wall of the tumor itself. I should like to entertain the pos-

sibility of tuberculosis. It would be rather unusual to find a localized tuberculous lesion in the transverse colon without ulceration or some other evidence of the disease in the cecum and ascending colon. Also, we would expect to find more evidence of tuberculosis in the terminal ileum. At least, it is a possibility that is hard to dismiss in view of obstruction in a young man with evidence of an inflammatory process. There are other inflammatory processes that we might think of, actinomycosis for example. He may have had some other form of cancer. The tumor might have been caused by a neoplasm of the lymphoma series, a lesion involving the wall of the transverse colon plus a large, broken-down mass of nodes in the region of the cecum. I cannot narrow it down to any finer diagnosis than that.

DR. LELAND S. MCKITTRICK: I am more confused than Dr. Fish was. May I ask Dr. Hampton whether he believes, as stated here, that there was an ulcerating lesion in the ileocecal region?

DR. HAMPTON: No, the x-ray report stated that the mucosal pattern in the transverse colon over an 8-cm. area was destroyed. I said that I thought it was fair to say that we cannot at times determine whether the mucosa is destroyed or not. Where the colon is this small, due to any disease, the mucosal pattern cannot be demonstrated. You have to be able to spread it out to demonstrate the pattern.

DR. GEORGE W. HOLMES: Dr. Hampton, do not some of our cases with infection show edema of the mucosa? Such a condition would eliminate the normal mucosal pattern.

DR. HAMPTON: Yes, an inflammatory process could do the same thing.

DR. FRANKLIN J. BALCH, JR.: Under any circumstance, do you not have to think of appendiceal abscess and spasm of the transverse colon as being responsible for that defect?

DR. FISH: I did not seriously consider an appendiceal abscess because the sequence of events suggested obstruction followed by inflammatory complications rather than the other way around. Furthermore, because of the attachments of the meso-ileum and meso-cecum, it is rather unusual to have an appendiceal abscess that pushes the ileum downward from a position medial to the cecum.

#### PREOPERATIVE DIAGNOSIS

Carcinoma of colon with perforation

#### DR. FISH'S DIAGNOSIS

Carcinoma or lymphoma of colon with perforation and localized abscess

#### ANATOMICAL DIAGNOSES

Subacute appendicitis

Appendiceal abscess

#### PATHOLOGICAL DISCUSSION

DR. RICHARD H. WALLACE: My preoperative diagnosis was cancer of the colon with perforation. On exploration there was no peritonitis, but there was a mass that involved the cecum, ascending colon and the right part of the transverse colon. The terminal ileum was involved in the mass and was so markedly dilated and obstructed that I did a preliminary operation—an ileotransversostomy. A week later we explored again, planning to do a right colectomy. In freeing up the tip of the cecum we identified a thick, porky appendix, so we removed it. The appendix crossed over the terminal ileum, obstructed the latter and lay behind and medial to the ascending colon with the tip at the spot in the transverse colon which showed the defect by x-ray. It was long, and the distal portion was entirely necrotic. At the time of operation the abscess, if there had been one, had been absorbed.

DR. MALLORY: You noted just before the second operation that the mass seemed smaller than it was previously?

DR. WALLACE: Yes. My impression on opening the abdomen the first time was that the mass was malignant. The lateral gutter was free and the mass was movable.

I should have said he had an x-ray check later, which showed a normal colon.

DR. HAMPTON: I have proof here that the colon was normal after operation. This is the same area in the transverse colon which was abnormal before operation.

A PHYSICIAN: Did the fecal stream go the normal way or through the ileostomy?

DR. HAMPTON: I do not have the report but believe that it went both ways.

## PNEUMONIA AND THE HEALTH OF THE NATION

PHYSICIANS in their capacity of citizens of the United States may be divided in their opinions as to the wisdom of the extension of governmental activities in various phases of the practice of medicine. However, it cannot be denied that much valuable service is being rendered to the medical profession and, both directly and indirectly, to the health of the nation by a number of governmental agencies. Foremost among such agencies stands the United States Public Health Service which already had many notable achievements to its credit.

One of the more recent interests of the United States Public Health Service, following the creditable pioneer activities in that field conducted under the auspices of the Massachusetts Department of Public Health, has concerned pneumonia. In

undertaking to co-ordinate, on a national basis, the various pneumonia-control programs already under way or being contemplated in the various states, it was necessary first to obtain reliable information concerning the extent and importance of the problem. The National Health Survey conducted by the United States Public Health Service, with the aid of a financial grant from the Works Progress Administration, has recently brought to light useful information in this respect.

In a recent release\* it is stated that the reports are based on a house-to-house canvass of some 800,000 families, including 2,800,000 persons, in eighty-three cities and twenty-three rural areas in nineteen states, during the winter of 1935-1936. The total surveyed population was so distributed as to give a sample which was, in general, representative of cities of the United States according to size and region. In large cities (100,000 and over) the population to be canvassed was determined by random selection of many small districts based on those used in the United States Decennial Census of 1930. In the small cities selected for the study, the population was enumerated completely. The data covered a period when the death rate of pneumonia was neither high nor low in comparison with the average for a seventeen year period.

The practicing physician during the height of the season may be called on to care for one or, at most, a small number of patients with pneumonia. A few excerpts from the report of this survey may help him to appreciate the significance of the disease in its broader perspective. Incidentally, some of the findings again bring to a focus the problems of the cost of medical care.

The pneumonia case rate among families on relief was found to be over twice that among families in the upper income groups. There was also an excess in the rates among families who were not on relief but whose incomes were less than \$125 per month.

Pneumonia, which disables more than 5 out of every 1000 persons in urban communities during

\*Release (No. 16-27) from the United States Public Health Service dated February 3, 1939.

the course of a year, was most prevalent among children and old persons. The annual frequency rate of pneumonia among children under three years of age was 18 per 1000 and among persons sixty-five years and over 11 per 1000, while the rate among youths and young adults (fifteen to forty-four years) was only 3 per 1000.

It is stated that men, from birth to old age, are more likely to have pneumonia than are women. For men, the annual frequency rate was found to be 6.0 per 1000, while it was only 4.9 for women. The greatest excess in the male over the female rate, 48 per cent, occurred in the youth group (fifteen to twenty-four years). In the other age groups the excesses ranged from 16 to 24 per cent, with the exception that among persons sixty-five years and over, the rates showed no appreciable difference by sex.

The average duration of disability of non-fatal pneumonia cases was observed to be forty-two days, and of fatal cases nineteen days. For all pneumonia cases—fatal and non-fatal—the average period of disability was thirty-nine days. Previous bulletins issued by the National Health Survey gave durations for acute illnesses (disabling for a week or longer) as forty-six days for accidents, twenty-four days for infectious diseases and nineteen days for all respiratory causes. The director points out that a comparison of these figures shows that pneumonia ranks among the most severe acute diseases.

In issuing this report the United States Public Health Service warns that early diagnosis with prompt and continuous medical care is recognized as extremely important if the severe course of pneumonia is to be lessened and death prevented. While the services of a doctor are indispensable in the proper treatment of pneumonia, the federal health authorities also point out the important role of proficient bedside nursing in the management of this disease and the necessity of hospital care for some cases. Previous *Public Health Reports* have stressed the need for wide and speedy application of serum therapy but have also called attention to the high cost of treatment, whether it includes serum or not. The conclusions drawn

from the National Health Survey are to the effect that those in the high-income groups are given relatively good care, regardless of the size of city in which they live, while those in the low-income groups are less well cared for in the small communities than they are in the large.

## FURTHER LIGHT ON CHILDHOOD TUBERCULOSIS

A CONTRIBUTION by Smith, published last year in the *Journal*,\* deserves thoughtful consideration, particularly in view of the very decided change in attitude toward childhood tuberculosis that has come into existence in late years. Primary tuberculosis in childhood, once believed to sound the doom-tocsin for that individual, is now recognized as fundamentally a benign process. Even tuberculosis in infancy, seriously as it still must be considered, is nevertheless far from exacting the high and immediate toll of life that was once attributed to it.

In both infancy and childhood, tuberculosis mortality continues to decrease rapidly, more rapidly, however, in infancy, where the mortality is also still the higher. What are the dangers that still accompany these infections? How can they best be met? This is the problem that Smith seeks to cast light on by a study of the 345 deaths due to tuberculosis that occurred in the Infants' and Children's hospitals in Boston from 1923 through 1937.

One death occurred from tuberculosis for every 59 infants admitted to the Infants' Hospital, where the age limit is two years, in the Children's Hospital, admitting patients from two to twelve years of age, 1 death occurred from tuberculosis for every 95 admissions. The majority of the infants died with both milary tuberculosis and tuberculous meningitis, 20 per cent with pulmonary tuberculosis or tuberculous pneumonia, only 10 per cent with tuberculous meningitis alone. In the two-to-seven-year group 63 per cent died of the combined lesions, and 32 per cent of meningitis alone, in the seven-to-twelve-year group only 8 per cent died of milary tuberculosis and 75 per cent of meningitis.

Smith, C. A. The dangers of tuberculosis in childhood. *New Eng. J. Med.* 219:260-265 1933.

alone In the older groups no pulmonary lesions were found in those coming to autopsy

The inference drawn is that once an infected individual has safely passed the years of infancy, there is relatively little chance of dying of tuberculosis until the adolescent years, with their increased risk of reinfection, are reached Deaths due to meningitis unaccompanied by miliary tuberculosis may be regarded as unpredictable accidents, resulting from the rupture of a previously unsuspected central-nervous-system focus

The child with a primary tuberculous infection, then, requires not sanatorium care or restricted activity, but only intelligent oversight, with periodic x-ray examinations of the chest and life in an environment free from the possibility of further exposure and reinfection Herein, also, lies the wisdom of a careful system of case finding, for every individual with tuberculosis due to infection with the human type of bacillus received it from another individual, and in further exposure lies his greatest danger

#### POSTPARTUM HEMORRHAGE LACERATION OF THE CERVIX

Mrs. M. C., a seventeen-year-old primipara, was admitted to the hospital at term on November 18, 1915, in active labor For five days before entry she had been having irregular, uncomfortable abdominal pain, which was probably due to an irritable uterus Twelve hours previous to entry these pains had become more marked and closer together

Her past history was negative except for the usual childhood diseases Catamenia began at twelve, were regular with a twenty-eight to thirty-day cycle and lasted four days Her last menstrual period was February 12, making the expected date of confinement November 19 The family history was irrelevant

Her present pregnancy had been entirely normal There had been no albuminuria, hyper-

tension or symptoms suggestive of toxemia of pregnancy The general physical examination on entry revealed no abnormalities The heart was not enlarged, there were no murmurs or arrhythmias The blood pressure was 104 systolic, 78 diastolic The lungs were clear and resonant The chest showed normal expansion The uterine contractions were irregular, but the uterus relaxed well between contractions The head was fully engaged and in ODA position The fetal heart rate was 140, heard in the left lower abdominal quadrant The membranes were intact A rectal examination revealed the cervix to be two and a half fingers dilated and of soft consistence The pelvic measurements were I C 25.5 cm, I S 25 cm, E C 18 cm, outlet 8.5 cm

Immediate delivery was deemed advisable by the doctor in charge of the case because of fear of the development of a contraction ring in view of the length of time the patient had had uterine contractions The patient was therefore anesthetized with ether, and the cervix was manually dilated A forceps was applied over the baby's ears Great difficulty was encountered in drawing the head through the cervix After one hour of hard pulling at regular intervals the cervix finally split laterally, following which the head was readily extracted The baby breathed and cried normally following its delivery An examination of the perineum revealed a third-degree laceration The placenta and membranes were expressed intact on the sixth uterine contraction Bleeding was profuse, the patient lost well over 500 cc. of blood within a short time In order to control bleeding from the cervix, six catgut through and through sutures were placed in each side to close the bilateral lacerations, which apparently did not extend out into the vaults The perineum was then repaired, using chromic catgut and silk worm gut sutures The patient by this time was in moderately severe shock and was treated by administration of caffeine, heaters and a subpectoral infusion of 500 cc of normal salt solution She responded well, and the pulse rate rapidly came down to 120

The first eight days after delivery were complicated by a sustained febrile reaction, the temperature varying from 100 to 102.5°F Her temperature then became normal, and she was discharged on the twenty-first postpartum day The perineum at this time was healed The cervix was bilaterally scarred, while the vaults were free The uterus was anterior and well involuted

*Comment* This case is presented not only for its historical interest (it occurred twenty three years ago) but as an example of the near tragedy that so often follows meddlesome operating

A series of selected case histories by members of the section will be published weekly Comments and questions by subscribers are solicited and will be discussed by members of the section

As one reviews this case, one finds no reason whatever for doing anything to this patient. In 1915, just about the high point of the accouchement forcé era was reached. Familiarity breeds contempt, and so long as this patient survived the operation, the same procedure was probably repeated the next day. Since then, obstetrics has shown no more intelligent advance than an appreciation of the physiology of the cervix, and of the dictum that no patient should be delivered whose cervix is not fully dilated.

Tears like these may occur in normal labors, but serious tears that follow operative deliveries invariably mean poor judgment and bad obstetrics, neither of which should be tolerated by our present-day hospitals.

#### LEGISLATIVE NOTES

All members of the Massachusetts Medical Society should carefully read the bills printed below. A post card will be sent to each member on which he is to indicate his position in regard to the bills. The Council of the Society unanimously opposed H. 985 and H. 986. H. 60 was approved by the Council by a vote of 114 to 34. Facts concerning it were given on the editorial page last week. It has been agreed to delete the controversial phrase "such other information as the board may require" that has caused much adverse comment. It will strengthen the position of the Society before the legislature in other matters if we can show them that a large majority of the Society oppose the first two bills and favor the last.

CHARLES C. LUND, M.D., *Chairman*

\* \* \*

#### HOUSE BILL 985

AN ACT TO REQUIRE DOCTORS OF MEDICINE AND DOCTORS OF OSTEOPATHY ON THE BOARD OF REGISTRATION IN MEDICINE.

*Be it enacted by the Senate and House of Representatives in General Court assembled and by the authority of the same as follows:*

SECTION 1 Section ten of chapter thirteen of the General Laws, as amended by chapter eight of the acts of nineteen hundred and thirty two, is hereby further amended by adding to the first sentence the words — five of whom shall be doctors of medicine and two of whom shall be doctors of osteopathy, — so as to read as follows —

Section 10 There shall be a board of registration in medicine, in the two following sections called the board, consisting of seven persons, residents of the commonwealth, registered as qualified physicians under section two of chapter one hundred and twelve, or corresponding provisions of earlier laws, who shall have been for ten years actively engaged in the practice of their profession, five of whom shall be doctors of medicine and two of whom shall be doctors of osteopathy. No member of said board shall belong to the faculty of any medical college or university, and no more than three members thereof shall at one time be members of any one chartered state medical society. One member thereof shall annually in June be appointed by the governor, with the advice and consent of the council, for seven years from July first following.

SECTION 2 The provisions of this act shall become effective as of the time of the appointment for the term

beginning July first, nineteen hundred and thirty-nine, as to the first doctor of osteopathy, and, as of the time of the appointment for the term beginning July first, nineteen hundred and forty, as to the second doctor of osteopathy.

#### HOUSE BILL 986

AN ACT PROVIDING FOR A DOCTOR OF MEDICINE AND A DOCTOR OF OSTEOPATHY ON THE APPROVING AUTHORITY AND THE STATUS OF APPROVALS BY THE AMERICAN MEDICAL ASSOCIATION AND THE AMERICAN OSTEOPATHIC ASSOCIATION.

*Be it enacted by the Senate and House of Representatives in General Court assembled, and by the authority of the same, as follows:*

SECTION 1 Section two of chapter one hundred and twelve of the General Laws is hereby amended by striking out the first sentence, as appearing in section one of chapter two hundred and forty-seven of the acts of nineteen hundred and thirty six, and inserting in place thereof the following —

Each applicant who shall furnish the board with satisfactory proof that he is twenty-one or over and of good moral character, that he possesses the educational qualifications required for graduation from a public high school, that he has completed two years of premedical collegiate work, including physics, chemistry and biology, in a college or university approved by a body consisting of two members of the board, appointed by the chairman at the regular board meeting in July each year, who shall hold their offices for one year, one of whom shall be a doctor of medicine and the other a doctor of osteopathy, the commissioner of education and the commissioner of public health, herein referred to as the approving authority, that he has attended courses of instruction for four years of not less than thirty-two school weeks in each year, or courses which in the opinion of the board are equivalent thereto, in one or more legally chartered medical schools, and that he has received the degree of doctor of medicine, or its equivalent, from a legally chartered medical school, having the power to confer degrees in medicine and approved by the approving authority, shall, upon payment of twenty five dollars, be examined, and if found qualified by the board, be registered as a qualified physician and entitled to a certificate in testimony thereof, signed by the chairman and secretary.

SECTION 2 Section four of chapter two hundred and forty seven of the acts of nineteen hundred and thirty six is hereby amended by adding at the end thereof the following sentence —

And the approving authority shall approve all medical schools, which have the approval of the American Medical Association, and all osteopathic schools which have the approval of the American Osteopathic Association, unless the decision to the contrary by the approving authority is unanimous on the part of all its members.

#### HOUSE BILL 60

AN ACT REQUIRING THE ANNUAL LICENSING OF QUALIFIED PHYSICIANS

SECTION 1 Chapter one hundred and twelve of the General Laws, as appearing in the Tercentenary Edition thereof, is hereby amended by inserting after section four the following new section

SECTION 4A Every person registered as a qualified physician, who is engaged in the practice of medicine with in the commonwealth, shall annually in December trans-

alone In the older groups no pulmonary lesions were found in those coming to autopsy

The inference drawn is that once an infected individual has safely passed the years of infancy, there is relatively little chance of dying of tuberculosis until the adolescent years, with their increased risk of reinfection, are reached Deaths due to meningitis unaccompanied by miliary tuberculosis may be regarded as unpredictable accidents, resulting from the rupture of a previously unsuspected central-nervous-system focus

The child with a primary tuberculous infection, then, requires not sanatorium care or restricted activity, but only intelligent oversight, with periodic x-ray examinations of the chest and life in an environment free from the possibility of further exposure and reinfection Herein, also, lies the wisdom of a careful system of case finding, for every individual with tuberculosis due to infection with the human type of bacillus received it from another individual, and in further exposure lies his greatest danger

#### POSTPARTUM HEMORRHAGE LACERATION OF THE CERVIX

Mrs M C, a seventeen-year-old primipara, was admitted to the hospital at term on November 18, 1915, in active labor For five days before entry she had been having irregular, uncomfortable abdominal pain, which was probably due to an irritable uterus Twelve hours previous to entry these pains had become more marked and closer together

Her past history was negative except for the usual childhood diseases Catamenia began at twelve, were regular with a twenty-eight to thirty-day cycle and lasted four days Her last menstrual period was February 12, making the expected date of confinement November 19 The family history was irrelevant

Her present pregnancy had been entirely normal There had been no albuminuria, hyper-

tension or symptoms suggestive of toxemia of pregnancy The general physical examination on entry revealed no abnormalities The heart was not enlarged, there were no murmurs or arrhythmias The blood pressure was 104 systolic, 78 diastolic The lungs were clear and resonant The chest showed normal expansion The uterine contractions were irregular, but the uterus relaxed well between contractions The head was fully engaged and in ODA position The fetal heart rate was 140, heard in the left lower abdominal quadrant The membranes were intact A rectal examination revealed the cervix to be two and a half fingers dilated and of soft consistence. The pelvic measurements were I C 25.5 cm, I S 25 cm, E C 18 cm, outlet 8.5 cm

Immediate delivery was deemed advisable by the doctor in charge of the case because of fear of the development of a contraction ring in view of the length of time the patient had had uterine contractions The patient was therefore anesthetized with ether, and the cervix was manually dilated A forceps was applied over the baby's ears Great difficulty was encountered in drawing the head through the cervix After one hour of hard pulling at regular intervals the cervix finally split laterally, following which the head was readily extracted The baby breathed and cried normally following its delivery An examination of the perineum revealed a third-degree laceration The placenta and membranes were expressed intact on the sixth uterine contraction Bleeding was profuse, the patient lost well over 500 cc of blood within a short time In order to control bleeding from the cervix, six catgut through and through sutures were placed in each side to close the bilateral lacerations, which apparently did not extend out into the vaults The perineum was then repaired, using chromic catgut and silkworm gut sutures The patient by this time was in moderately severe shock and was treated by administration of caffeine, heaters and a subpectoral infusion of 500 cc of normal salt solution She responded well, and the pulse rate rapidly came down to 120

The first eight days after delivery were complicated by a sustained febrile reaction, the temperature varying from 100 to 102.5°F Her temperature then became normal, and she was discharged on the twenty-first postpartum day The perineum at this time was healed The cervix was bilaterally scarred, while the vaults were free The uterus was anterior and well involuted

## MISCELLANY

### CONFERENCE ON MEDICAL PATENTS

At the direction of the House of Delegates, the Board of Trustees of the American Medical Association has issued a call, in a letter to medical schools, pharmaceutical firms and other research agencies, for a national conference to consider problems involved in the patenting of products concerned with the prevention and treatment of disease and with public health in general.

This conference, to be held Thursday, March 16, at the headquarters of the American Medical Association, 535 North Dearborn Street, Chicago, will be presided over by Dr. Roger I. Lee, of Boston, a member of the Board of Trustees of the American Medical Association.

The first session will start at 10 a. m. and the second one at 2 p. m. on March 16. The various aspects of the subject of the call will be introduced by speakers familiar with them, followed by general discussion.

The theme of the conference is *The Administration of Medical Patents for the Public Welfare*. The proceedings will be published in full or in abstract in the *Journal of the American Medical Association*.

---

### YOUR HEALTH BROADCASTS

The next series of Your Health broadcasts, sponsored by the American Medical Association and the National Broadcasting Company and heard over the Blue Network each Wednesday at 2:00 p. m., is entitled *Community Health*. It consists of four broadcasts as follows:

**March 8. Water, Waste and Sanitation**

Importance of community control of water supplies, sewage disposal and general sanitary matters.

**March 15. Guarding Fresh Foods**

What the community can and must do to protect fresh foods, such as fish, fruits, vegetables, meats, bakery goods.

**March 22. Auditing the Health Record**

The meaning and the importance of vital statistics, contagious disease reporting and community health records.

**March 29. Animal Diseases Transmitted to Man**

Rabbit fever, rabies, undulant fever and similar infections, and what can be done about them.

---

### MEDICAL HISTORY NOTES

A second Graduate Week in Medical History will be held under the auspices of the Institute of the History of

Medicine at the Johns Hopkins University, Baltimore, April 24 to 29. The first Graduate Week, held in April, 1938, was attended by thirty-three members from sixteen states and Canada.

For the present session, one lecture will be given every morning by members of the staff of the Institute of the History of Medicine, and the afternoons will be devoted to informal round table seminars. As in the past, several exhibitions will be held. The general subject to be considered during the Graduate Week is *The Renaissance*.

Following the meeting at Baltimore, the annual meeting of the American Association of the History of Medicine will take place in Atlantic City. The council of the association will meet on April 30, and the annual meeting will take place with a special program on May 1. It should be noted that the *Bulletin of the Institute of the History of Medicine*, published by Johns Hopkins University, is now the official organ of the American Association of the History of Medicine.

---

## CORRESPONDENCE

### CONVALESCENT CARE

*To the Editor*—The editorial in the recent number of the *Journal* interests me greatly, and I am much pleased to see that the *Journal* is recognizing the great need of this type of professional care of our patients. The tendency of late, of course, has been to hasten the discharge of the patients from the hospitals, either the medical cases or the surgical cases, with the result that many of them are sent out in a relatively very poor condition of health.

The whole question of convalescence is very little understood by the active profession today, and I know of no field in which there are greater opportunities for scientific research than that which concerns the physiology of the convalescent. The younger members of the hospital staffs have very little appreciation of all that is involved in this and pay very little attention to the patients after they are discharged from the wards. The older men, as a rule, understand much more about that which convalescence represents, realizing from empirical experience, perhaps, that which helps people to recovery and appreciating, at the same time, the personality of individuals upon which so much of health depends.

With properly organized convalescent hospitals there would be a wonderful opportunity for some of the older members of the profession, who, perhaps, are not equal to the strain of active service in general hospitals but who could continue for many years the direction of convalescent hospitals, and bring their years of experience to very practical usefulness in this work. With the chronic patient, especially the arthritic class that very greatly needs convalescent hospital type of care, the opportunity for service by experienced physicians is very great. Undoubtedly one reason why the convalescent hospitals connected with the general hospitals of Boston were discontinued was that the only medical care that the patients received there was given by the house officers in the very beginning of their hospital connection before they had had any real experience in handling patients and when they were entirely unprepared for treating patients at the time when the greatest medical skill is oftentimes needed.

Another feature, of course, which it seems to me should be considered is the fact that as hospitals are being built today, the costs, as I understand it, are from \$5,000 to \$10,000 a bed, while a convalescent hospital could be built so that

mit to the board a license fee of two dollars together with a statement made on a blank furnished by the board at his request and signed by him under the penalties of perjury, giving his name, his registration number, the date of his registration, and his professional address, provided that such statement may be so transmitted at any time prior to April first next following upon the payment of a license fee of two dollars together with a further fee of one dollar for each month or part thereof that he is in default, and provided further that every registered qualified physician who withdraws from the practice of medicine within the commonwealth shall be exempt from transmitting such license fee or statement during the time of such withdrawal if he notifies the board in writing of such intended withdrawal. After such a withdrawal and prior to re-entering the practice of medicine within the commonwealth, every qualified registered physician shall transmit to the board a license fee of two dollars and the statement aforesaid. The board shall give to each qualified registered physician transmitting the fee and statement hereunder a certificate stating that he has complied with the provisions of this section and he shall display such certificate continuously in a conspicuous place in his office during the period covered by such certificate. Every person registered by the board as a qualified physician, who is engaged in the practice of medicine within the commonwealth, shall notify the board promptly of any change of his professional address, giving his new address in writing. Whoever, being duly registered under section two or corresponding sections of earlier laws, practices medicine within the commonwealth without complying with the requirements of this section, shall be punished by a fine of not less than five nor more than one hundred dollars.

#### MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning March 6

##### BARNSTABLE

Sunday, March 12, at 4 00 p m., at the Cape Cod Hospital, Hyannis. Subject—Heart Disease The treatment of 'heart attacks' or 'cardiovascular emergencies'. Instructor Samuel A Levine. Donald E Higgins, *Chairman*

##### BERKSHIRE

Thursday, March 9, at 4 30 p m., at the House of Mercy Hospital, Pittsfield. Subject—Bright's Disease and Hypertension. Evaluation of new therapy, diagnosis. Instructor Laurence B Ellis. Melvin H. Walker, Jr., *Chairman*

##### BRISTOL NORTH

Thursday, March 9, at 4 00 p m., at the Morton Hospital, Taunton. Subject—The Control and Treatment of Respiratory Infections. (This is to include the serological treatment of pneumonia in infants and children.) Instructor Harold A. Higgins. Lester E. Butler, *Chairman*

##### BRISTOL SOUTH (Fall River Section)

Tuesday, March 7, at 4 00 p m., at the Union Hospital, Fall River. Subject—Anemia. Modern methods in diagnosis and treatment of blood

dyscrasias. Instructor Clark W Heath. Howard P Sawyer, *Chairman*

##### FRANKLIN

Wednesday, March 8, at 8 00 p m., at the Franklin County Public Hospital, Greenfield. Subject—Heart Disease. The treatment of 'heart attacks' or 'cardiovascular emergencies'. Instructor Francis L Chamberlain. Halbert G Stetson, *Chairman*

##### HAMPDEN

Thursday, March 9, at 4 00 p m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8 00 p m., in the Outpatient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. Subject—Heart Disease. The treatment of 'heart attacks' or 'cardiovascular emergencies'. Instructor Francis L Chamberlain. George L. Schadt, *Chairman*

##### MIDDLESEX EAST

Tuesday, March 7, at 4 00 p m., at the Melrose Hospital (Colby Hall), Melrose. Subject—Gonorrhea. Modern treatment of gonorrhea. Instructor George C Prather. Walter H Flanders, *Chairman*

##### MIDDLESEX NORTH

Thursday, March 9, at 4 30 p m., at St. John's Hospital, Lowell. Subject—Delivery and the Puerperium. Instructor Christopher J Duncan. William S Lawler, *Chairman*

##### MIDDLESEX SOUTH

Tuesday, March 7, at 5 00 p m., at the Cambridge Hospital, 330 Mt. Auburn Street, Cambridge. Subject—Bright's Disease and Hypertension. Evaluation of new therapy, diagnosis. Instructor W Richard Ohler. Alexander A Levi, *Chairman*

#### DEATHS

HARRINGTON—DANIEL J HARRINGTON, M.D., of 760 Columbia Road, Dorchester, died February 20. He was in his fifty third year.

A graduate of Harvard University in 1906, he received his degree from Tufts College Medical School in 1910. Dr Harrington was on the staff of the Boston City Hospital and the Carney Hospital and had practiced medicine in Boston for twenty nine years. He had been medical examiner for the Massachusetts Bonding Insurance Company and the Southern Indemnity Company for the past two years and had recently been active at the eye clinic of the Cambridge City Hospital.

Among his affiliations were fellowships in the Massachusetts Medical Society and the American Medical Association.

His widow, three sons, a daughter and a brother survive him.

SUPPLE—EDWARD A SUPPLE, M.D., of 385 Marlborough Street, Boston, died February 26. He was in his fifty seventh year.

Born in Holliston he graduated from Boston College in 1903 and received his degree from the Harvard Medical School in 1907. Dr Supple had served as surgeon at the Boston City, Lying-in and St. Elizabeth's hospitals, and

## REPORT OF MEETING

## NEW ENGLAND PATHOLOGICAL SOCIETY

A meeting of the New England Pathological Society was held at the Evans Memorial on October 21, 1938, Dr Charles Branch presiding. Dr Leroy U Gardner, director of pathology at the Saranac Hospital, presented the paper of the evening, speaking on the subject *Silicosis*. He described the investigations carried on in his laboratory as to the pathogenesis of lesions produced by silica and its various compounds. The reaction of the lung to inhaled dusts is not necessarily fibrous in character, and the effects produced by dusts on lung tissue are not peculiar to the lung itself. Injections of dusts into any part of the body will produce lesions similar to those observed in pulmonary tissue. Intravenous injections of aqueous suspensions of dust particles were made into the ear veins of rabbits, and the changes that occurred in various organs were studied. There was a tendency for the particles to localize in the liver, spleen, lymph nodes and bone marrow, and marked reactions were observed in all these tissues. A variety of dust particles were utilized in the study: pure silica, silicates, non-siliceous minerals and mixtures of silica and other minerals.

The changes occurring in the liver were cited as examples of those occurring in the other organs. Pure silica produced nodules of connective-tissue proliferation similar in appearance to tubercles, although caseation necrosis did not occur. Such nodules were formed within one month after institution of injections. After a longer time interval a laminated, hyaline nodule with an area of necrosis around its periphery was observed, and still later there was diffuse fibrosis throughout the entire organ. Colloidal silica produced relatively little reaction. There was chronic inflammation about small groups of phagocytic histiocytes, and the lesions were retrogressive rather than progressive, never resulting in fibrous tissue proliferation. The previously held belief that quartz exerted its pathogenic effect by dissolving to form silicic acid, which acted as the etiologic agent of fibrosis, is no longer tenable. Silica gel produced mild chronic inflammatory reactions which were retrogressive. Colloidal silicic acid was toxic and produced death. Amorphous silica caused some degree of fibrosis, which also tended to retrogress, although permanent changes were more marked than those produced by the gels. Diatomite produced changes which were indistinguishable from those of quartz. The degree of tissue reaction to silica was found to be inversely proportional to the size of the injected particles.

The combined silicas or silicates did not possess the same irritative power as that shown by silica. Lesions produced by them were foreign-body reactions and were non-progressive. Non-siliceous minerals produced similar reactions. A few silicates (talc, mica, asbestos) produced chronic inflammation without fibrosis.

It was concluded from these experiments that crystal line and cryptocrystalline forms of silica were capable of producing a progressive fibrosis of specific character and that a few of the amorphous forms also produce fibrosis of lesser degree. None of the silicates were capable of producing fibrosis.

When silica was injected together with non-siliceous particles, for example anthracite, there was inhibition of fibrosis, an effect which might be explained by the hypothesis that the non-siliceous material coated the silica and protected it from the action of the body fluids.

Inhalation experiments were performed in which guinea pigs inhaled various types of dusts. Silicosis was

produced in these animals which was identical with that observed in human beings. By mixing quartz with gypsum or other materials these animals were protected against marked fibrosis. This apparent protection was explained by analyses of lung ash which showed that the percentage of silica in the tissue was much less than that in the animals which had been exposed to an equal concentration of pure silica dust. This indicated that the animals retained less silica when it was mixed with gypsum than they did when exposed to an atmosphere in which silica alone was suspended.

These observations explain why some theoretical industrial dust hazards have failed to be actual ones. The total amount of silica inhaled from a high concentration of mixed dusts may not be so great as that inhaled in a lower concentration of pure silica dust. The amount of various dusts deposited in the lungs is not proportional to the proportion of these dusts in the atmosphere. Furthermore, the percentage of silica in the air is not proportional to that of silica in the material from which the dust arises.

In summary, Dr Gardner stated that every case of pneumoconiosis did not necessarily manifest itself by a fibrous reaction, but might show only a slight degree of chronic inflammation. Other minerals associated with quartz in the atmosphere may inhibit or delay the action of silica on the body. Various external factors in the atmosphere may tend to decrease the amount of silica inhaled, and the chemical determination of the amount of silica in rafted dust is not necessarily an indication of the amount of silica in the atmosphere in the area. Finally, chemical factors in the body may retard or influence the tissue reaction to silica.

In the discussion Dr Philip Drinker stated that 2 per cent of all industrial employees in the United States are exposed to dusts but that only 0.2 per cent inhale dusts containing silica. Some 4000 or 5000 workers have silicosis to a disabling extent.

In answer to a question, Dr Gardner said that there was no experimental evidence that alkalis, for example soap powders, accelerated the progress of silicosis. The apparent clinical evidence indicating such acceleration is explained by the fact that workers exposed to silica and soap powder are subjected to silica dust in which the particles are extremely fine, and hence result in a more rapid progress of fibrosis.

Spun glass when powdered and injected intravenously produced a reaction similar to that caused by other silicates, namely chronic inflammation.

Some workers have claimed that the addition of silica to culture mediums inoculated with tubercle bacilli accelerated their growth, but Dr Gardner on repeated attempts has been unable to confirm this observation. In the lung, however, tubercle bacilli grow well in areas of necrosis due to silica, and there is marked localization of bacilli in areas in which silica has been injected.

Patients with both silicosis and tuberculosis show a very high fatality rate. Of the cases at Saranac which give a history of exposure to dusts, 65 per cent of those exposed to silica have active tuberculosis, while only 15 per cent of those exposed to non-siliceous dusts have active tuberculous lesions.

The action of silica in causing activation of an old tuberculous lesion may be due to the fact that silica particles are carried into the tubercle and cause an acceleration of the growth of the bacilli, while a necrosis develops in the surrounding tissues, allowing a spread of the multiplying tubercle bacilli, with subsequent advance of the infection.

it would probably not average more than \$1,000 a bed. The saving which this would represent in our hospital budgets would, of course, be very great.

There is a great opportunity for study along the lines suggested by your editorial, and I am very glad that you have put this challenge before the profession

JOEL E. GOLDTHWAIT, M.D.

372 Marlborough Street,  
Boston

#### A CORRECTED BOOK REVIEW

*To the Editor* In the review of the book entitled *Your Chest Should Be Flat* published in the February 9 issue of the *Journal*, the sentence, 'The author may be able to prove his point if he follows the group of apparently normal children in whom he found round, deep, chests, and later cites a lower incidence of tuberculosis in these patients as compared with that in those who were flat-chested, should read a greater incidence.

The reviewer also intended to convey the thought that the author should have done chest measurements on healthy children only, and given the incidence of tuberculosis later on in life among those with deep chests as compared with those with flat chests

MOSES J. STONE, M.D.

Boston

This first error was occasioned by careless editing in the *Journal* office — Ed

#### DISEASE OF BESNIER-BOECK-SCHAUMANN

*To the Editor* I hesitate to reopen the controversial history of the disease of Besnier-Boeck-Schaumann, however, the article in your January 26 issue by Leon Babalian has recalled my attention to it.

Your readers will perhaps remember the article by Francis T. Hunter in your journal on February 20, 1936, by title, 'Hutchinson-Boeck's Disease,' in which he devoted several pages to the historical background of this disease and credited Jonathan Hutchinson with the first report of a case in 1875. I shall not go into that period and merely wish to point out that the credit which Hunter gives to Hutchinson and to Boeck, and which Babalian gives to Boeck and Besnier, adding that Pautrier has enlarged the nosological picture of Schaumann and has identified it with an affection of the reticuloendothelial system, belongs to Dr. J. Schaumann, the director of the Finsen Institute in Stockholm.

The entire question seems to me to have been adequately settled by Professor J. Tillgren's article on Schaumann's disease (lymphogranulomatosis benigna) in the *Acta Medica Scandinavica* (93:189-208, 1937). To quote from him, "We also find in the literary survey [of this disease] that some authors do not understand the difference between isolating and establishing on a firm basis the individuality of a disease and on the other hand publishing casuistic observations of it with a few vague guesses added to the same. He is referring to Schaumann's first published work on lupus pernio in a memoir presented in November, 1914, to the French Society of Dermatology for the Zambaco Prize, in which he classified into a disease *sui generis* lymphogranulomatosis benigna because of the following symptoms: multiple adenopathies, tonsillar changes, changes in the marrow, occasional enlarge-

ment of the spleen and liver, previously unknown changes in the lungs, changes in the blood picture, and skin changes.

For years Pautrier disagreed with Schaumann's conception of this disease, and it does not seem fair from the standpoint of historical accuracy that these other men should receive the credit and Schaumann should be let down with the single sentence in Babalian's article that he claimed that they [lupus pernio and Boeck's sarcoid] were manifestations of the same disease, which he called benign lymphogranulomatosis.

#### ERRONEOUS REPORT

*To the Editor* On page 266 of the February 9 issue of the *New England Journal of Medicine* there is a report of remarks by me on 'Recent Observations on Chronic Industrial Benzol Poisoning' made before the Suffolk District Medical Society. I note that there are several glaring errors in the report, which have completely changed my meaning in several places. I shall not attempt to make corrections, but call attention to the fact that my paper, when published, should be consulted and no attention paid to this stenographic report.

FRANCIS T. HUNTER, M.D.

6 Commonwealth Avenue,  
Boston

#### ARTICLES ACCEPTED BY THE AMERICAN MEDICAL ASSOCIATION COUNCIL ON PHARMACY AND CHEMISTRY

*To the Editor* In addition to the articles enumerated in our letter of January 15 the following have been accepted:

##### Abbott Laboratories

Ampules Thiamin Chloride 10 mg., 1 cc.  
Ampules Thiamin Chloride 100 mg., 1 cc.

##### Diarsenol Co., Inc.

Bismuth Subsalcylate in Oil Suspension

##### Merck & Co., Inc.

Stovarsol Tablets, 0.1 gm.  
Stovarsol Tablets, 0.05 gm.  
Scopolamine Hydrobromide Merck  
Scopolamine Hydrobromide Crystals-Merck  
Scopolamine Hydrobromide Powder Merck  
Solution of Formaldehyde Merck

##### National Drug Company

Anatumeningococcic Serum, Refined and Concentrated

##### Sharp & Dohme

## REPORT OF MEETING

### NEW ENGLAND PATHOLOGICAL SOCIETY

A meeting of the New England Pathological Society was held at the Evans Memorial on October 21, 1938, Dr Charles Branch presiding. Dr Leroy U Gardner, director of pathology at the Saranac Hospital, presented the paper of the evening, speaking on the subject Silicosis. He described the investigations carried on in his laboratory as to the pathogenesis of lesions produced by silica and its various compounds. The reaction of the lung to inhaled dusts is not necessarily fibrous in character, and the effects produced by dusts on lung tissue are not peculiar to the lung itself. Injections of dusts into any part of the body will produce lesions similar to those observed in pulmonary tissue. Intravenous injections of aqueous suspensions of dust particles were made into the ear veins of rabbits, and the changes that occurred in various organs were studied. There was a tendency for the particles to localize in the liver, spleen, lymph nodes and bone marrow, and marked reactions were observed in all these tissues. A variety of dust particles were utilized in the study: pure silica, silicates, non-siliceous minerals and mixtures of silica and other minerals.

The changes occurring in the liver were cited as examples of those occurring in the other organs. Pure silica produced nodules of connective tissue proliferation similar in appearance to tubercles, although caseation necrosis did not occur. Such nodules were formed within one month after institution of injections. After a longer time interval a laminated, hyaline nodule with an area of necrosis around its periphery was observed, and still later there was diffuse fibrosis throughout the entire organ. Colloidal silica produced relatively little reaction. There was chronic inflammation about small groups of phagocytic histiocytes, and the lesions were retrogressive rather than progressive, never resulting in fibrous tissue proliferation. The previously held belief that quartz exerted its pathogenic effect by dissolving to form silicic acid, which acted as the etiologic agent of fibrosis, is no longer tenable. Silica gel produced mild chronic inflammatory reactions which were retrogressive. Colloidal silicic acid was toxic and produced death. Amorphous silica caused some degree of fibrosis, which also tended to retrogress, although permanent changes were more marked than those produced by the gels. Diatomite produced changes which were indistinguishable from those of quartz. The degree of tissue reaction to silica was found to be inversely proportional to the size of the injected particles.

The combined silicas or silicates did not possess the same irritative power as that shown by silica. Lesions produced by them were foreign body reactions and were non progressive. Non siliceous minerals produced similar reactions. A few silicates (talc, mica, asbestos) produced chronic inflammation without fibrosis.

It was concluded from these experiments that crystalline and cryptocrystalline forms of silica were capable of producing a progressive fibrosis of specific character and that a few of the amorphous forms also produce fibrosis of lesser degree. None of the silicates were capable of producing fibrosis.

When silica was injected together with non siliceous particles, for example anthracite, there was inhibition of fibrosis, an effect which might be explained by the hypothesis that the non-siliceous material coated the silica and protected it from the action of the body fluids.

Inhalation experiments were performed in which guinea pigs inhaled various types of dusts. Silicosis was

produced in these animals which was identical with that observed in human beings. By mixing quartz with gypsum or other materials these animals were protected against marked fibrosis. This apparent protection was explained by analyses of lung ash which showed that the percentage of silica in the tissue was much less than that in the animals which had been exposed to an equal concentration of pure silica dust. This indicated that the animals retained less silica when it was mixed with gypsum than they did when exposed to an atmosphere in which silica alone was suspended.

These observations explain why some theoretical industrial dust hazards have failed to be actual ones. The total amount of silica inhaled from a high concentration of mixed dusts may not be so great as that inhaled in a lower concentration of pure silica dust. The amount of various dusts deposited in the lungs is not proportional to the proportion of these dusts in the atmosphere. Furthermore, the percentage of silica in the air is not proportional to that of silica in the material from which the dust arises.

In summary, Dr Gardner stated that every case of pneumoconiosis did not necessarily manifest itself by a fibrous reaction, but might show only a slight degree of chronic inflammation. Other minerals associated with quartz in the atmosphere may inhibit or delay the action of silica on the body. Various external factors in the atmosphere may tend to decrease the amount of silica inhaled, and the chemical determination of the amount of silica in rafter dust is not necessarily an indication of the amount of silica in the atmosphere in the area. Finally, chemical factors in the body may retard or influence the tissue reaction to silica.

In the discussion Dr Philip Drinker stated that 2 per cent of all industrial employees in the United States are exposed to dusts but that only 0.2 per cent inhale dusts containing silica. Some 4000 or 5000 workers have silicosis to a disabling extent.

In answer to a question, Dr Gardner said that there was no experimental evidence that alkalis, for example soap powders, accelerated the progress of silicosis. The apparent clinical evidence indicating such acceleration is explained by the fact that workers exposed to silica and soap powder are subjected to silica dust in which the particles are extremely fine, and hence result in a more rapid progress of fibrosis.

Spun glass when powdered and injected intravenously produced a reaction similar to that caused by other silicates, namely chronic inflammation.

Some workers have claimed that the addition of silica to culture mediums inoculated with tubercle bacilli accelerated their growth, but Dr Gardner on repeated attempts has been unable to confirm this observation. In the lung, however, tubercle bacilli grow well in areas of necrosis due to silica, and there is marked localization of bacilli in areas in which silica has been injected.

Patients with both silicosis and tuberculosis show a very high fatality rate. Of the cases at Saranac which give a history of exposure to dusts, 65 per cent of those exposed to silica have active tuberculosis, while only 15 per cent of those exposed to non siliceous dusts have active tuberculous lesions.

The action of silica in causing activation of an old tuberculous lesion may be due to the fact that silica particles are carried into the tubercle and cause an acceleration of the growth of the bacilli, while a necrosis develops in the surrounding tissues, allowing a spread of the multiplying tubercle bacilli, with subsequent advance of the infection.

it would probably not average more than \$1,000 a bed. The saving which this would represent in our hospital budgets would, of course, be very great.

There is a great opportunity for study along the lines suggested by your editorial, and I am very glad that you have put this challenge before the profession.

JOEL E. GOLDTHWAIT, M.D.

Boston

#### A CORRECTED BOOK REVIEW

*To the Editor* In the review of the book entitled *Your Chest Should Be Flat* published in the February 9 issue of the *Journal* the sentence, "The author may be able to prove his point if he follows the group of apparently normal children in whom he found round, deep, chests, and later cites a lower incidence of tuberculosis in these patients as compared with that in those who were flat chested," should read "a greater incidence."

The reviewer also intended to convey the thought that the author should have done chest measurements on healthy children only, and given the incidence of tuberculosis later on in life among those with deep chests as compared with those with flat chests.

#### DISEASE OF BESNIER-BOECK-SCHAUMANN

*To the Editor* I hesitate to reopen the controversial history of the disease of Besnier-Boeck-Schaumann, however, the article in your January 26 issue by Leon Babalian has recalled my attention to it.

Your readers will perhaps remember the article by Francis T. Hunter in your journal on February 20, 1936, by title, 'Hutchinson-Boeck's Disease,' in which he devoted several pages to the historical background of this disease and credited Jonathan Hutchinson with the first report of a case in 1875. I shall not go into that period and merely wish to point out that the credit which Hunter gives to Hutchinson and to Boeck, and which Babalian gives to Boeck and Besnier, adding that Pautrier has enlarged the nosological picture of Schaumann and has identified it with an affection of the reticuloendothelial system, belongs to Dr. J. Schaumann, the director of the Finsen Institute in Stockholm.

The entire question seems to me to have been adequately settled by Professor J. Tillgren's article on Schaumann's disease (lymphogranulomatosis benigna) in the *Acta Medica Scandinavica* (93: 189-208, 1937). To quote from him, "We also find in the literary survey [of this disease] that some authors do not understand the difference between isolating and establishing on a firm basis the individuality of a disease and on the other hand publishing casuistic observations of it with a few vague guesses added to the same." He is referring to Schaumann's first published work on lupus pernio in a memoir presented in November, 1914, to the French Society of Dermatology for the Zambaco Prize, in which he classified into a disease *sui generis* lymphogranulomatosis benigna because of the following symptoms: multiple adenopathies, tonsillar changes, changes in the marrow, occasional enlarge-

ment of the spleen and liver, previously unknown changes in the lungs, changes in the blood picture, and skin changes.

For years Pautrier disagreed with Schaumann's conception of this disease, and it does not seem fair from the standpoint of historical accuracy that these other men should receive the credit and Schaumann should be let down with the single sentence in Babalian's article that "he claimed that they [lupus pernio and Boeck's sarcoid] were manifestations of the same disease, which he called benign lymphogranulomatosis."

Columbus, Ohio

#### ERRONEOUS REPORT

*To the Editor* On page 266 of the February 9 issue of the *New England Journal of Medicine* there is a report of remarks by me on 'Recent Observations on Chronic Industrial Benzol Poisoning' made before the Suffolk District Medical Society. I note that there are several glaring errors in the report, which have completely changed my meaning in several places. I shall not attempt to make corrections, but call attention to the fact that my paper, when published, should be consulted and no attention paid to this stenographic report.

FRANCIS T. HUNTER, M.D.

6 Commonwealth Avenue,  
Boston

#### ARTICLES ACCEPTED BY THE AMERICAN MEDICAL ASSOCIATION COUNCIL ON PHARMACY AND CHEMISTRY

*To the Editor* In addition to the articles enumerated in our letter of January 15 the following have been accepted:

##### Abbott Laboratories

- Ampules Thiamin Chloride 10 mg, 1 cc.
- Ampules Thiamin Chloride 100 mg, 1 cc.

##### Diarsenol Co., Inc.

- Bismuth Subsalcylate in Oil Suspension

##### Merck & Co., Inc.

- Stovarsol Tablets, 0.1 gm.
- Stovarsol Tablets, 0.05 gm.
- Scopolamine Hydrobromide Merck
- Scopolamine Hydrobromide Crystals-Merck
- Scopolamine Hydrobromide Powder Merck
- Solution of Formaldehyde Merck

##### National Drug Company

- Antimeningococcic Serum, Refined and Concentrated

## NOTICES

### ANNOUNCEMENT

MORRIS YORSHIS, M.D., announces the opening of an office at 281 Haverhill Street, Lawrence.

### PROFESSOR BEST TO LECTURE

Professor C. H. Best, of the Department of Physiology, University of Toronto, will speak on Recent Work on Experimental Diabetes, with Particular Reference to the Anterior Pituitary Gland at Sanders Theatre, Harvard University, on Thursday evening, March 9, at 8:15.

In this talk, sponsored by the Diabetes Committee of the Massachusetts Tuberculosis League, Dr. Best will discuss the new experimental diabetes, first produced by Young in London, his own contribution to that work, and his recent experiments.

This fresh adventure in the etiology of diabetes is certainly the most notable since the original discovery of the cause of diabetes by Von Mering and Minkowski in 1889. The lecture is open without charge to physicians, medical students, pre-medical students, nurses, and others on the personal introduction of physicians.

### JOHN T. BOTTOMLEY SOCIETY

A meeting of the John T. Bottomley Society of the Carney Hospital Out Patient Department will be held on Tuesday, March 7, at 11:30 a.m.

Dr. John L. Doherty will speak on Treatment of Acute Back-Strain.

WILLIAM J. MACDONALD, M.D., *Secretary*

### AMERICAN PHYSICIANS ART ASSOCIATION

The American Physicians Art Association, composed of members in the United States, Canada and Hawaii, will hold its second art exhibit in the City Art Museum of St. Louis, May 14-20, during the annual session of the American Medical Association. Art pieces will be accepted for this art show in the following classifications: (1) oils, both portraits and landscapes, (2) water colors, (3) sculpture, (4) photographic art, (5) etchings, (6) ceramics, (7) pastels, (8) charcoal drawings, (9) book-binding, (10) wood carving, (11) metal work (jewelry). Practically all pieces sent in will be accepted. There will be over sixty valuable prize awards. For details of membership in this association and rules of the exhibit kindly write to Max Thorek, M.D., Secretary, 850 Irving Park Boulevard, Chicago, Illinois, or F. H. Redewill, M.D., President, 521-536 Flood Building, San Francisco, California.

### GREATER BOSTON MEDICAL SOCIETY

A meeting of the Greater Boston Medical Society will be held in the Beth Israel Hospital Auditorium on Tuesday evening, March 7, at 8:15.

Dr. Maxwell Finland will speak on "The Present Status of the Specific Treatment of Pneumococcal Pneumonia and Other Pneumococcal Infections." There will be a discussion by Drs. Frederick T. Lord, Edward Curnen and Mark F. Leses.

LOUIS M. FREEDMAN, M.D., *President*  
DAVID B. STEARNS, M.D., *Secretary*

### THE FOUNDATION PRIZE

The American Association of Obstetricians, Gynecologists and Abdominal Surgeons announces that the annual

Foundation Prize for this year will be \$100. Those eligible include only interns, residents or graduate students in obstetrics, gynecology and abdominal surgery and physicians (M.D. degree) who are actually practicing or teaching obstetrics, gynecology or abdominal surgery.

Competing manuscripts must be presented in triplicate under a nom-de-plume to the secretary of the association before June 1, be limited to 5000 words and such illustrations as are necessary for a clear exposition of the thesis and be typewritten (double spaced) on one side of the sheet, with ample margins.

The successful thesis must be presented at the next annual (September) meeting of the association, without expense to the association and in conformity with its regulations.

For further details, address Dr. James R. Bloss, Secretary, 418 Eleventh Street, Huntington, West Virginia.

### WEST ROXBURY MEDICAL ASSOCIATION

A meeting of the West Roxbury Medical Association will be held at Highland Hall, 1868 Centre Street, West Roxbury, on Tuesday evening, March 7, at 8:30.

An illustrated lecture, Interesting Case Records, will be presented by Drs. John J. Elliott, William C. Maloney, John C. V. Fisher and Charles J. E. Kickham.

DAVID L. LIONBERGER, M.D., *Secretary*

### BOSTON DOCTORS SYMPHONY ORCHESTRA

*Nicolas Slonimsky*

Rehearsals of the newly organized Boston Doctors Symphony Orchestra, conducted by Nicolas Slonimsky, are held every Thursday evening at 7:30 at Hampton Court Hotel, 1223 Beacon Street, Brookline.

Membership is still open. All physicians, dentists and medical and dental students who are interested should communicate with Dr. Julius Loman, Pelham Hall Hotel, Brookline (BEA 2430).

### BOSTON CITY HOSPITAL

The monthly clinicopathological conference will be held at the Boston City Hospital on Wednesday, March 8, at 12 o'clock noon, in the Pathological Amphitheater.

JOSEPH E. HALLISEY, M.D., *Secretary*  
Medical Staff

### SOUTH END MEDICAL CLUB

The next meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, March 21, at 12 o'clock noon. Dr. Halsey B. Loder will speak on Neglected Gall Bladder Disease.

Physicians are cordially invited to attend.

JOHN B. HALL, M.D., *Secretary*

### BOSTON LYING IN HOSPITAL

The next Journal Club meeting of the Boston Lying in Hospital will be held on Wednesday, March 15, at 8:30 p.m.

## SYMPOSIUM ON PLACENTATION

Presentation of Six Human Presomite Embryos Dr John I Brewer, Northwestern University Medical School, Chicago, Illinois Discussion by Dr George B Wislocki and Dr Arthur Herzig

Physicians and students are cordially invited to attend

DUNCAN E REID, M.D., Secretary

## AMERICAN ASSOCIATION FOR THE STUDY OF GOITER

The next annual meeting of the American Association for the Study of Goiter will be held in Cincinnati Ohio May 22, 23 and 24 The program for this meeting will consist of scientific papers dealing with goiter and other diseases of the thyroid gland, dry clinics conducted by guests of the association and operative clinics in the various hospitals in Cincinnati.

The Van Meter Prize Award of three hundred dollars and two honorable mentions for the best essays submitted concerning original work on problems related to the thyroid gland will be made at this meeting, provided essays of sufficient merit are presented in competition

The competing essays may cover either clinical or research investigations should not exceed three thousand words in length must be presented in English and a typewritten double spaced copy sent to the corresponding secretary, Dr W Blair Mosser, 133 Biddle Street, Kane, Pennsylvania, not later than April 15 The committee that will review the manuscripts is composed of men well qualified to judge the merits of the competing essays

A place will be reserved on the program of the annual meeting for presentation of the Prize Award Essay by the author if it is possible for him to attend The essay will be published in the annual proceedings of the association. This will not prevent its further publication however, in any journal selected by the author

## MEDICAL CLINIC AT THE PETER BENT BRIGHAM HOSPITAL

At 3 30 p m on Thursday, March 9 in the amphitheater of the Peter Bent Brigham Hospital, Dr Robert T Monroe associate in medicine, Harvard Medical School and physician Peter Bent Brigham Hospital will give a medical clinic Practitioners and medical students are cordially invited to attend

## TUMOR CLINIC BOSTON DISPENSARY

Each Tuesday and Friday morning 10 00 to 12 30 there is a meeting of the Tumor Clinic of the Boston Dispensary a unit of the New England Medical Center Neoplasms of various sorts are seen and discussed and when there is an indication are treated with radium of high voltage x ray Physicians are invited to visit this clinic They may bring patients for aid in diagnosis or may refer patients to the clinic following which a report will be returned to the referring physician A limited number of beds are available for diagnostic study and for treatment

## SOCIETY MEETINGS AND CONFERENCES

## CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY MARCH 6

## MONDAY MARCH 6

- 4 p m Physicians and medical students are cordially invited to attend a clinic presented by the medical surgical and orthopedic services of the Infants and Children's hospitals, in the amphitheater of the Children's Hospital
- 5 p m Edward K Dunham lecture Harvard Medical School amphitheater Building C

## TUESDAY MARCH 7

- 9-10 a m Joseph H Pratt Diagnostic Hospital Diagnosis and Treatment of Certain Bone Tumors. Dr J D Adams
- 10 a m 12 30 p m Tumor clinic Boston Dispensary
- 11 30 a m John T Bottomley Society Carney Hospital Out Patient Department
- 8 15 p m Greater Boston Medical Society Beth Israel Hospital auditorium
- 8 30 p m West Roxbury Medical Association Highland Hall 1865 Centre Street West Roxbury

## WEDNESDAY MARCH 8

- 9 10 a m Joseph H Pratt Diagnostic Hospital Hospital case presentation Dr S J Thannhauser
- 12 m Clinicopathological conference. Children's Hospital amphitheater
- 12 m Boston City Hospital Monthly clinicopathological conference. Pathological amphitheater
- 5 p m Edward K Dunham lecture Harvard Medical School amphitheater Building C

## THURSDAY MARCH 9

- New England Hospital Association. Hotel Statler
- 8 30-9 30 a m Exchange visit Surgical and Orthopedic Staffs of the Peter Bent Brigham and Children's hospitals held this week at the Children's Hospital Surgical
- 9 10 a m Joseph H Pratt Diagnostic Hospital Laboratory Aids in the Detection of Gonococcus Infection. Dr W A Hinton
- 3 30 p m Medical clinic at the Peter Bent Brigham Hospital
- 8 15 p m Professor Best to Lecture. Sanders Theater Harvard University

## FRIDAY MARCH 10

- New England Hospital Association. Hotel Statler
- \*9 10 a m Joseph H Pratt Diagnostic Hospital Functional Disturbances of the Gastrointestinal Tract Dr J H Means
- \*10 a m 12 30 p m Tumor clinic Boston Dispensary
- 5 p m Edward K Dunham lecture. Harvard Medical School amphitheater Building C

## SATURDAY MARCH 11

- New England Hospital Association Hotel Statler
- 9 10 a m Joseph H Pratt Diagnostic Hospital Hospital case presentation Dr S J Thannhauser
- \*10 a m 12 m Staff rounds of the Peter Bent Brigham Hospital Conducted by Dr Henry A Christian

## SUNDAY MARCH 12

- 4 p m Illustrated public health lecture Faulkner Hospital auditorium Arthritis Causes and treatment. Dr Lloyd T Brown
- 4 p m Free public lecture. Harvard Medical School Amphitheater of Building D Hazards in the Modern Home. Dr Timothy Leary

 business and scientific sessions

## BOOK REVIEWS

*The 1938 Year Book of Physical Therapy* Edited by Rich-  
 ard Kovacs 486 pp Chicago The Year Book Pub-  
 lishers, Inc., 1938 \$2.50

This is the first year book on physical therapy to be published and as such will be welcomed by those interested in this special field of medicine. It gauges the progress made by clinicians and men of research, as is reflected in the abstracts of papers published here and abroad. Some papers go a step farther by forecasting progress. Thus one states 'A yeast culture increases its fermentation in the positron ray and stops in the electron ray. The behavior of bacteria is similar. The fact that the course of a chemical process can be retarded or accelerated at will with electron or positron radiation points to the possibility of the control of pathologic metabolic processes and of the capillary circulation at the site of the disease.'

Another paper describes the role played by the Council on Physical Therapy in reporting on the value and merit of all therapeutic and certain diagnostic apparatus and contrivances offered for sale to physicians and hospitals.

Short wave diathermy is introduced by an editorial statement in regard to the various claims which have been made by different observers concerning the mode of action of this therapeutic measure. These include thermic, athermic, bactericidal and selective effects. Evidence pro and con in regard to these claims is presented in the abstracts. These also contain detailed statements with regard to dosage, technic of application and choice of apparatus.

Artificial fever therapy is taken up. The physiopathological aspects of this form of treatment are discussed, to be followed by a paper entitled 'Posology of Therapeutic Fever,' in which are discussed the nature, intensity, duration and frequency of induced fever therapy. The various cabinets which are employed in the administration of this treatment are described, and illustrated by cuts.

Under the general heading of 'Light Therapy' we find papers on heliotherapy and ultra violet light radiation. The quartz mercury and carbon-arc lamps are described and

illustrated. There is a great variety of papers dealing with such phases of the subject as 'Histamine Content of the Skin after Ultra-Violet Radiation,' 'Effects of Ultra Violet Rays and Visible Rays on Carbohydrate Metabolism,' 'Effects of Heliotherapy on Osteogenesis,' 'Clinical Applications of Ultra-Violet Ray on Wound Healing and 'Ultra-Violet Air Sterilization.'

The second part of the book deals with the treatment of various pathologic conditions by the physical agents described in the first part.

This first attempt has proved that there is sufficient worthwhile material accumulating to encourage the continuance of such a publication.

 Fr fr

This is a provocative little book in which the author classifies and studies various forms of vague, fickle and generally unrecognized manifestations of a latent type of tuberculosis. He claims that the disease, instead of localizing in a particular organ, masquerades for years, in certain instances for a lifetime, under the colorless and loose fitting mantle of various clinical entities, such as chronic erythema, sarcoid, acne, acrocyanosis, chilblains, some types of chronic rheumatism, localized or diffuse cellulitis, multiple sclerosis and vague psychopathies.

The author studied three main entities. He describes first a migrating type of chronic military tuberculosis, 'passing from one organ to the other, often from one serous membrane to the other, and disappearing spontaneously without leaving any important sequelae.' Then comes the state of chronic bacillosis with subnormal temperatures for months and years, chronic invalidism, absence of any permanent important, localized tuberculous focus sufficient to explain the general condition, and a marked predominance among women. Assumption of the etiology is based on tuberculous antecedents and a strongly positive tuberculin reaction. The third and last group, the author calls *patraques*, which means a machine which functions badly because it is poorly built or worn out. These patients differ from those of the preceding category. Their state is more stabilized. The symptomatology lacks precision, it assumes the various clinical pictures resulting from a lack of equilibrium of the main systems and may be mistaken for a dysfunction of any of them. These are cases of constitutional debility that are physically below par from birth, remain so all their lives, and never look or feel well, yet, there are rarely if ever any definite positive findings. The symptoms are vague, and the examinations and tests unsatisfactory. The complaints vary from day to day and cover a wide range—thoracic pains, digestive disturbances, abdominal discomfort, constipation, migraine, insomnia, nervousness, depression, and so forth.

Intelligent management and proper treatment can do a good deal in a certain percentage of cases. Psychotherapy comes first. Symptoms are dealt with as they arise. The physician must aim to build up those patients by all the resources that hygiene, exercise and diet put at his disposal. Sanatorium treatment has little to offer, gold salts less. The author claims to have obtained good results with tuberculin injections which are continued for six to eight months.

This book opens attractive avenues of speculation which any internist should be glad to follow. He may find among them some helpful suggestions to meet with more equanimity and better understanding some of his trying cases of chronic disease.

## THE CLINICAL EFFECT OF COLLOIDAL ALUMINUM HYDROXIDE ON PATIENTS WITH PEPTIC ULCER\*

ROBERT B. RUTHERFORD, M.D.† AND EDWARD S. EMERY, JR., M.D.‡

BOSTON

THE most difficult problem which confronts the practitioner today in the treatment of patients with peptic ulcer is that of deciding as to the severity of the disease. This condition, like arthritis and many other chronic ailments, varies astonishingly in its intensity. From 40 to 50 per cent of the cases prove to be mild and do not require more than a simple form of therapy. Thirty to 40 per cent are only moderately severe and are controlled by a moderately strict regime. This leaves 15 to 20 per cent of the cases which tax the physician's skill to the utmost, because they respond unsatisfactorily to ordinary procedures, both medical and surgical. Alkalies are usually ineffective in neutralizing the gastric juice sufficiently for them to be of any value, and frequently have to be stopped because of the development of alkalosis. The less radical operations, such as gastroenterostomy and partial resection, frequently leave the patient worse than before because of the formation of jejunal ulcers. These results are so unfortunate that one of us (E. S. E. Jr.<sup>1</sup>) in 1934 cautioned against the use of surgery, and suggested that it was better to do the best one could with prolonged rest and frequent feedings, since the results, although admittedly unsatisfactory, were better than the complications following the usual surgical procedures. In recent years there has been an attempt to solve the problem by radical surgery, with the result that an increasing number of gastric resections are being performed. However, this solution is not altogether satisfactory. There is no gainsaying that many patients on whom a large resection has been done suffer from unpleasant symptoms caused by the overburdening of the upper intestine with food. Epigastric distress of varying degrees, weakness, and

faintness after meals are some of the sequelae. Dilatation of the jejunum and looseness of the bowels may occur. Moreover, information on the final results of this operation is too meagre for us to forecast ultimate results. We have had 3 cases of gastric resection at the Peter Bent Brigham Hospital in which jejunal ulcers developed. Even radical surgery leaves much to be desired in the handling of severe cases.

In view of this unsatisfactory state of affairs, we have been led to investigate the possible value of aluminum hydroxide in the treatment of severe cases, and wish to report on the clinical results which we have had with it to date. We<sup>2</sup> have previously reported its effect on the gastric juice. It is known to be an effective antacid, and is free from the disadvantages of absorbable alkalies, which may produce alkalosis.<sup>3</sup>

The latter quality should be of the greatest value in treating severe cases characterized by an excessive secretion of hydrochloric acid. The experimental work of Mann and Williamson<sup>4</sup> has shown that this acid bears an important relation to peptic ulcer. One of us (E. S. E. Jr.<sup>5</sup>) has already emphasized the value of temporarily inhibiting a hypersecretion by x-ray. If the reported effect of aluminum hydroxide on secretion can be confirmed, the acidity can be more effectively controlled by this drug than by the more familiar alkalies. During the day the very severe case secretes large quantities of gastric juice with a high concentration of acid, and this process continues at night, long after the stomach has emptied itself of food (an abnormality characteristic of patients with ulcer). The usual ulcer regime which is designed to neutralize the acid by means of frequent feedings and alkaline powders, is unsatisfactory in many patients with hypersecretion. Owing to the large amounts of alkali required to neutralize the excessive secretion of acid, alkalosis is a frequent complication, particu-

From the Medical Clinic of the Peter Bent Brigham Hospital.

\*Assistant resident physician, Peter Bent Brigham Hospital.

†Instructor in medicine, Harvard Medical School; associate in medicine, Peter Bent Brigham Hospital.

larly when the usual sodium and calcium powders are used. The stomach responds to them by an increased secretion, and a vicious cycle develops. The more alkali the greater is the secretion, until a point is reached where the onset of alkalosis compels discontinuance of the powders. Even if it is possible to neutralize the secretion during the day, it is frequently impossible to overcome the night secretion, the seriousness of which is not always fully recognized. But the fact is that ulcers do not heal in the presence of a night secretion, even though the gastric juice is neutralized during the day.

The properties of colloidal aluminum hydroxide should make it an ideal preparation for controlling hypersecretion. The amount of the drug that can be prescribed is not limited by the possibility of alkalosis. Therefore, sufficient quantities can be given to neutralize all the acid. The drug may be allowed to drip into the stomach continuously through a tube,<sup>7</sup> so that neutralization can be maintained throughout every day and night from the very beginning of treatment. If the drug inhibits the secretion of acid, the complication of night secretion should be easily overcome.

#### MATERIAL AND METHODS

We chose for this study only the severe cases which had proved refractory to previous medical or surgical treatment or both. We treated 28 patients. Eighteen of these were admitted to the wards of the Peter Bent Brigham Hospital, 10 were treated in the Out-Door Department and were ambulatory throughout their treatment. Sixteen patients represented the severest type of the disease, while 12 were classified as moderately severe. In 15 of the severest cases there was excessive hypersecretion, and in 12 of these the symptoms were never controlled satisfactorily, following one or more treatments on the hospital wards with the usual Sippy regimen. Four patients, who for economic or social reasons had never been hospitalized, had not responded to ambulatory treatment. Four of the severe cases had suffered previous perforations, 1 of these had experienced a perforation from a gastric ulcer and later one from a duodenal ulcer. One patient had had sixteen hospital admissions. Five had had previous surgery, in 2 cases this was followed by jejunal ulcers, and in 3 by continued severe pain. One of the severe cases was complicated by nephrolithiasis, which limited the amount of absorbable alkalis that could be used. The 12 moderately severe cases were so classified either because symptoms continued during an otherwise satisfactory ambulatory treatment, or because treatment with alkali-

line powders was considered inadvisable. Four of these patients had developed alkalosis previously while taking only a moderate amount of ordinary alkalis, and 2 suffered from renal calculi.

The following procedure was carried out in all cases. A gastric analysis was performed before starting the aluminum hydroxide. This consisted of a fractional study after an alcohol test meal. Following the completion of this test, histamine was given routinely and continuous drainage was instituted for one hour, in order to determine the quantity of juice secreted in response to the chemical stimulation. After satisfactory tests of the gastric juice had been completed, the patients who had been hospitalized were started on a continuous drip of colloidal aluminum hydroxide. The preparation which was used is known as Creamalin\*. One part of the aluminum hydroxide to three parts of water was used, and the mixture was allowed to drip into the stomach at the rate of approximately 15 drops per minute. In addition to the antacid the patients received 90 cc. of equal parts of milk and cream every hour, and supplementary feedings were gradually introduced until by the end of the first week six small meals were being taken. The drip was continued day and night for a week, at the end of which it was omitted for twenty-four hours and another gastric analysis was performed. If at this time the patient's gastric acidity had not been reduced markedly, the drip was continued for several more days. When it was finally discontinued, the patients were given 60 cc of diluted aluminum hydroxide every hour from 8 a m to 9 p m and the six small feedings were changed to three moderate-sized meals. The procedure in the ambulatory cases was similar to that of the hospital cases except that the drip treatment was omitted. These patients were seen at weekly intervals, for the most part, for from three to nine months. At each visit a gastric analysis was performed, and the amount of aluminum hydroxide was gradually reduced, so that by the end of three months the patients were receiving 90 cc before each meal and at bedtime.

#### RESULTS

All the patients in this series who received drip therapy, and all except 2 of those receiving ambulatory treatment, were relieved of their distress within twenty-four hours and had no recurrence of pain during the rest of the treatment. Some of the patients who had received the usual Sippy treatment reported that their stomachs felt "easier" under the aluminum hydroxide therapy than with

\* Supplied through the courtesy of the Cleveland Chemical Association, Cleveland, Ohio, and later of the Albia Pharmaceutical Company, Inc., 125 West 42nd Street, New York City.

alkaline powders (Several patients not included in this series refused the treatment because they objected to the tube or to the taste of the drug) We also found that aluminum hydroxide decreased the titratable acidity of the gastric juice The highest free acidity after the alcohol test meal dropped from an average of 68 before treatment to approximately 35 after treatment The total acidity followed the free acidity in all cases There was a similar drop in the acidity of the fasting contents and of the gastric juice secreted in response to histamine Our experience showed that usually a week was required for the acid to reach its lowest level, and that a continuance of the drip beyond this time caused little further decrease in the titratable acidity Patients who were given aluminum hydroxide by mouth reached the same low level after a somewhat longer period Frequent aspirations of the stomach during the day and at midnight showed that there was no free hydrochloric acid in the stomach while the patient was being given aluminum hydroxide

#### DISCUSSION

Our experience with this series has convinced us that it is possible to secure and maintain complete neutralization of gastric acidity if colloidal aluminum hydroxide is given in large enough amounts The evidence which we have to date indicates that this is an easy way to obtain quick relief in patients with severe ulcer symptoms The patient soon becomes accustomed to the small nasal tube and is able to eat and sleep without discomfort The present evidence also suggests that this method may be a valuable aid in the treatment of patients with hypersecretion or night secretion or both The rapid relief from pain throughout the twenty-four hours ensures for nervous patients an opportunity to relax, and since the patients in most of the severe cases are nervous, this is an important consideration The drip method ensures at the earliest moment the three requisites for healing, namely physical rest, nervous relaxation and neutralization of gastric acidity The inhibitory effect which the drug has on the secretion of hydrochloric acid should also decrease the harmful influence of hypersecretion However, there are a number of different factors that have to be considered in this connection, and we have formed no definite opinion

The question naturally arises why the aluminum hydroxide decreases the titratable acidity We studied histologically the mucous membranes of 2 patients who had been receiving the drip for four days and for three weeks, respectively No abnormalities were observed microscopically Fur-

thermore, the data presented by others give no contraindications to the use of aluminum hydroxide so far as its absorption and its effect on other organs are concerned Another point of interest is the length of time for which the decreased acidity can be maintained We have not yet accumulated sufficient data to answer this question However, the evidence so far gathered shows that there is a tendency for the acidity to start rising shortly after the continuous drip is stopped Further time is needed in order to determine whether it is possible to prevent a return to pretherapeutic levels by the administration of quantities of the drug which are practical over long periods of time

The types of patients for whom aluminum hydroxide is recommended are as follows

Those with peptic ulcer of an obviously severe type and with marked hypersecretion (This method brings them under control more rapidly and more completely than does any other)

Those who have not responded well to the usual medical treatment but have not yet been submitted to surgery

Those with a postoperative jejunal ulcer which has responded less well to therapy than did the original ulcer (The 2 patients of this type in the present series appeared to do better with aluminum hydroxide therapy than with alkaline powders)

Those with peptic ulcer associated with nephrolithiasis (The use of aluminum hydroxide makes it possible to treat the ulcer without danger of intensifying the renal difficulty)

#### SUMMARY AND CONCLUSIONS

We treated 28 patients with severe peptic ulcer by colloidal aluminum hydroxide This was given orally or by a combination of a continuous drip and the oral method for three to nine months It was found that the gastric contents were completely neutralized Relief of pain occurred within twenty-four hours The drug and the method of treatment were agreeable to the majority of patients The drug apparently did not alter the body chemistry

It is suggested that this form of treatment is advantageous in cases which do not respond well to the usual medical treatment because of a hypersecretion or night secretion, in cases complicated by nephrolithiasis, and in patients who develop alkalosis while receiving alkaline powders

## PAINLESS ACUTE INFARCTION OF THE HEART\*

ANDREW M BABEY, M.D.†

BROOKLYN, NEW YORK

SINCE Herrick<sup>10</sup> first emphasized in this country the frequency and classic features of coronary occlusion, this disorder has been a topic of unusual appeal to many workers. A vast amount of clinical and experimental observation has gradually made for a better understanding of the disease. Pain as a symptom of acute infarction possesses a very special interest, for it is by a study of its severity, site and radiation that one is most often led to make the correct diagnosis. It is therefore not a little surprising to find a great difference of opinion in the literature regarding this important presenting symptom.

Obrastzow and Straschesko<sup>20</sup> were among the first to point out that acute infarction of the heart could be painless. Since then, many have confirmed the fact.<sup>23</sup> More recently, efforts have been made to go farther and determine the relative incidence of painless and painful attacks. Parkinson<sup>21</sup> and Wolferth<sup>27</sup> believe that acute infarction without pain is very rare. Howard<sup>13</sup> found that in 6 per cent of a large series the patients had had no pain during their attacks. Davis,<sup>5</sup> who studied 76 case reports of old and recent infarcts, found no record of pain in 38 per cent. Saphir et al<sup>23</sup> discovered a similar percentage in their 34 cases. Boyd and Werblow,<sup>2</sup> after questioning over 100 consecutive patients with coronary thrombosis, stated that 33 per cent had had no pain. Kennedy<sup>15</sup> reviewing 200 necropsies and clinical histories, found that only 40 per cent of the cases with acute infarction had experienced no pain, while in 22.5 per cent of old healed infarctions no note of pain was made. Bean<sup>1</sup> examined 300 protocols and found a record of pain in only 72 per cent of acute infarctions, in about 25 per cent of all the cases, painless and painful, there was some clouding of the sensorium.

The fact of painless infarction having been established, there appeared some interesting speculation regarding the cause of this unusual phenomenon. Wearn,<sup>26</sup> Hamman,<sup>6, 7</sup> and Parkinson

and Bedford<sup>22</sup> state that when infarction supervened in a case with pre-existing signs and symptoms of heart failure, pain might be absent. Bruenn, Turner and Levy,<sup>3</sup> on the other hand, believed that those patients with no symptoms prior to the acute episode were most likely to have no pain associated with the thrombosis. Libman,<sup>16</sup> Carr,<sup>4</sup> and Keefer and Resnik<sup>14</sup> emphasized the alleged hyposensitivity of these patients. Davis<sup>5</sup> explained his cases by assuming an absolute rather than a relative ischemia of heart muscle at the time of infarction. Hay<sup>8, 9</sup> thought pain was likely to be absent in second and third attacks. Mullen<sup>19</sup> and Sutton<sup>24, 25</sup> were inclined to believe that painless attacks had some correlation with slowness of closure or smallness of vessels involved. Herrick<sup>11, 12</sup> thought certain areas of the heart were silent or less sensitive than others, or possibly that a gradual narrowing of an artery by sclerosis slowly destroyed vessels, nerves and functioning muscles, causing anesthesia in this part, so that a final complete obstruction came without a sudden shock—the heart being in a sense prepared for the supreme insult. Hochrein and Seggel<sup>28</sup> believed diabetic patients to be more prone to painless thrombosis.

From this brief review, it is obvious that there is great uncertainty not only about the cause of painless attacks but also about their incidence. This study was undertaken to obtain information only about the latter. It limits itself to acute infarcts diagnosed beyond question by characteristic serial electrocardiograms as well as clinical picture. All records were kindly placed at our disposal by the Electrocardiographic Department at Kings County Hospital.

Every case was seen by the writer as soon as possible after the diagnosis was established and a careful, unbiased history was taken. Whenever necessary the help of an interpreter was obtained. By direct questioning in each fresh case we hoped to avoid the difficulty which all previous writers, except Boyd and Werblow,<sup>2</sup> had encountered, namely the hazardous necessity of relying on statements recorded by people who might

From the Long Island College Medical Service, Kings County Hospital.

†Instructor in medicine Long Island College Medical School Brooklyn assistant attending physician Kings County Hospital

not have fully investigated each individual aspect of pain Libman's<sup>17</sup> styloid-process-pressure test to determine the presence or absence of sensitivity was used in many cases

Two objections promptly come to mind in such a study Have not certain mild, atypical cases escaped notice? Inasmuch as one or more electrocardiographic records are taken at Kings County Hospital on the slightest suspicion of abnormal heart action, it seems fair to state that this criticism is probably invalid The other objection is more difficult to surmount, for it depends, in part at least, on one's own interpretation of pain To overcome this, certain "criteria of pain" were laid down at the start, and when a patient experienced any one of these he was considered to have experienced a painful attack, though at times the patient himself might describe his sensation as "not exactly a pain" These standards were a burning, choking, bursting or boring sensation, squeezing, tightness or pressure, soreness, aching, numbness, simple heaviness or that associated with an obstructing lump, or a knifelike, sharp pain (uncommon)

Patients who died very suddenly before complete study, or those who were too sick to question and died soon after admission, were excluded, as were those who suffered infarction during operation or when barely out of anesthesia<sup>18</sup> Whenever the mental state was clouded on admission by uremia or impending coma and no reliable history was obtainable, the cases were considered unsatisfactory and omitted A small number of patients (5) had very bizarre or atypical electrocardiograms, particularly bundle-branch block Although the clinical history and rapid changes in electrocardiographic records indicated that these patients must surely have suffered an acute infarction, such cases were deliberately excluded, but all had pain at onset

In all, 116 cases were questioned and included in this study, and only 1 had painless infarction A summary of this case follows

L. M., a 43-year-old Jewish tailor, was admitted to the Kings County Hospital June 23, 1938, complaining of fainting after a sudden dizzy spell. A short time before entry he was sitting quietly in a chair when he suddenly became dizzy and fell to the floor unconscious. He was brought to the hospital by ambulance in a semistuporous state. Three years before admission he had had a severe substernal and precordial tightness, which his local doctor said was a heart attack. The patient stayed in bed about 6 weeks, after which he was apparently well, except for occasional attacks of angina pectoris on exertion No electrocardiogram was taken at that time.

Physical examination on admission revealed a semistuporous male complaining of headache. There was no noticeable dyspnea, orthopnea or cyanosis The blood pressure was 100/70 Moist rales were present at both

bases The heart sounds were of poor quality, the rhythm was regular No murmurs were heard The abdomen was slightly tender in both the right upper and right lower quadrants No peripheral edema was noted. Moderate pressure over the styloid process caused pain. A blood Wassermann test was negative, the urine showed many pus cells, which were interpreted as due to kidney infection, the patient having been operated on 2 years before for renal stone. Three electrocardiograms taken during the next month showed a T<sub>3</sub> type of infarction with progressive changes The patient left the hospital against advice after 1 month of bed rest.

Despite the number of papers stating that it is rather common, painless acute infarction of the heart is, in our experience, a rarity Almost all reports which declare it to be frequent are based on old case records which can be very misleading As Wolferth<sup>20</sup> has stated, patients who have suffered a coronary closure weeks or months before may have had such mild pain as to have completely forgotten about it Questioning all acute cases soon after the attack is the only safe approach Yet even this is liable to error, for patients occasionally suspect the nature of their attack and deny typical pain out of fear of being told the truth,<sup>21</sup> or their distress may not be classical and be entirely overlooked

#### SUMMARY

One hundred and sixteen patients with acute myocardial infarction admitted within the last year to Kings County Hospital were carefully questioned soon after their attacks, and, according to criteria set down in this paper, only 1 was found not to have had pain Furthermore, this patient gave a history suggesting strongly that three years before he had had a coronary occlusion with pain, and he reacted with pain to Libman's test for sensitivity

## A NEW METHOD OF STRAPPING FOR BACK STRAIN WITH SCIATICA\*

FREDERIC W ILFELD, M.D.†

BOSTON

**T**HIS report of a new method for treating back strain with sciatica is presented for consideration. The simplicity of the method and the prompt relief of pain in suitable subjects seem to warrant its further application.

The procedure was first considered in a patient with sciatica who volunteered the information that his pain was alleviated by walking with the leg in external rotation. This suggested that the pain might be due to spasm of the piriformis muscle. Consequently when, five months ago, a patient with pain in the lower back radiating down the leg was examined, a method of strapping the thigh and back with adhesive tape was devised to relieve tension on the muscles involved in the disability, namely the tensor fasciae latae, gluteus maximus and piriformis. The immediate relief of pain in this case led to its application to other patients.

### METHOD

The treatment consists of relieving the tension on these hip muscles by transferring the strain to the lower back by means of strips of adhesive tape applied along the thigh and back. It is very important to have the patient in the correct position

The subject lies on the unaffected side with the back toward the examiner (Fig 1). The legs are flexed 30 or 40 degrees, with the knees at a right angle, and several pillows are placed between the thighs to bring the upper or affected leg into 20 or 30 degrees of abduction and 20 or 30 degrees of external rotation. Three layers of adhesive tape

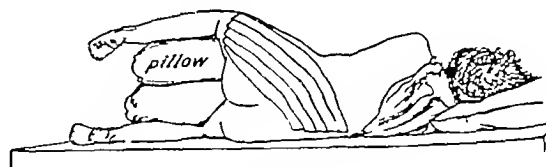

Figure 1

*Longitudinal strips of adhesive tape are placed on the thigh, hip and back, with the leg in 30 degrees of abduction, 40 degrees of flexion and 20 degrees of external rotation.*

are then applied. The first layer consists of long strips of 2-inch tape, as shown in the illustration. These are placed beginning 8 cm above the knee and about 5 cm from the middle of the anterior thigh. They are brought upward on the thigh, over the crest of the ilium 5 cm posterior to the anterior superior iliac spine, and continued onto the small of the back across the midline, as far superiorly as the twelfth dorsal vertebra. Similar

overlapping longitudinal strips are laid on the thigh, crossing the buttock and sacrum onto the lumbar region of the back, until the whole of the lateral thigh is covered. From below upward, transverse pieces of adhesive tape are fastened over the longitudinal strips covering the thigh, hip and lower back (Fig. 2). A third layer of tape is

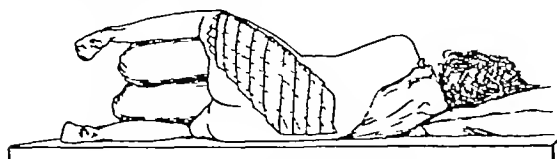

Figure 2

*From below upward transverse pieces of adhesive tape are fastened over the longitudinal strips covering the thigh, hip and lower back*

placed similar to the first longitudinal layer (Fig. 3). The leg is thereby strapped in abduction, flexion and external rotation, relieving the tension on the muscles involved in these actions, that is the tensor fasciae latae, gluteus maximus, and piriformis.

There has been no emphasis on aftercare except to advise the patients to refrain from heavy lifting or hard work. They have thus been kept ambulatory without the benefit of heat, salicylates, bed board or corset, in order to reach an estimate of the worth of this therapy uncomplicated, so far as possible, by other factors. The tape is removed after five to seven days. If the patient is symptom-free, no other treatment has been given except exercises for stretching the fascia lata. Should the Ober<sup>1</sup> or Ely<sup>2</sup> test on the opposite leg also be positive, and so give evidence of contracture of the fascia lata, or, should there be pain on internal rotation of the leg in the prone position, suggesting spasm of the piriformis muscle, that side may be treated in a similar fashion. In order to follow the progress of our patients and to measure the amount of contracture or tension on the fascia lata, the distance between the table and the knee was measured in the Ober test, similarly the distance between the buttock and heel was noted in the Ely test.

#### SELECTION OF CASES

Since this treatment is designed to relieve spasm of certain muscles only, it is important to select only those subjects in whom these structures appear to be involved. Patients with low back pain or sciatica are suitable subjects if they exhibit a positive Ober or Ely sign or pain on internal rotation of the leg in the prone position. Our patients were examined according to the method described by Smith-Petersen.<sup>3</sup> In half the cases roentgenographic studies were made. Lumbar punctures or lipiodol studies of the spine were not done. The

method has been used on 11 patients, with excellent results in 5, and considerable relief in the remainder. The following are representative case histories.

**Case 1** A 60-year-old housewife was seen in the Out-Patient Department in July, 1938, complaining of pain of 2 weeks' duration in the right sacroiliac region, radiating down the posterior aspect of the right thigh into the calf. Bed rest and ordinary back strapping had failed to relieve the pain. There was no history of trauma.

Examination showed a well-developed and moderately

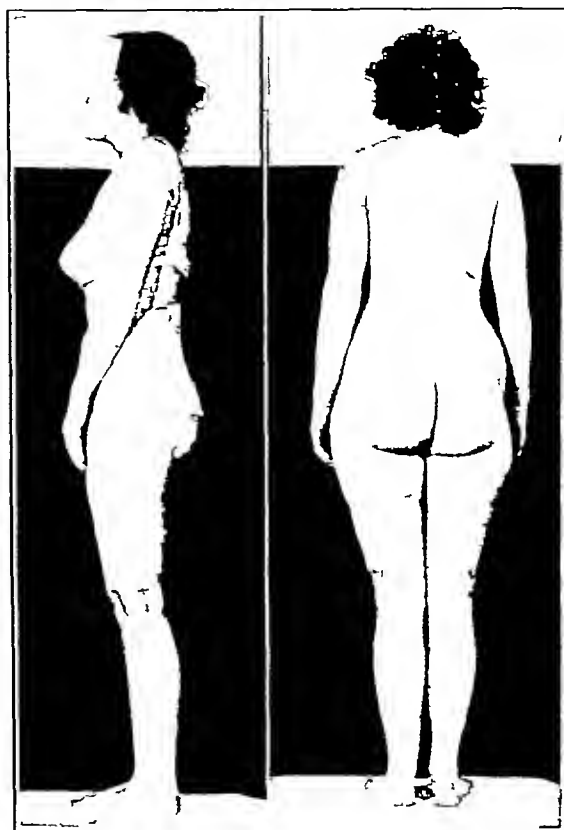

Figure 3

*Photographs showing adhesive strapping applied to relieve strain on the tensor fasciae latae, gluteus maximus and piriformis muscles. In the upright position, the anterior portion of the tape is tight, relieving strain on the tensor fasciae latae.*

obese woman. Flexion of the back while standing was limited to 20°. There was tenderness over the right posterior superior iliac spine. Straight leg raising on the right was limited to 45° by the onset of back pain. The Ober test on the right was positive. A diagnosis of back strain and sciatica due to contracted fascia lata on the right was made. It was believed that the underlying lesion was a spasm of the tensor fasciae latae, gluteus maximus and piriformis muscles. Accordingly the leg was strapped with adhesive tape in the manner described. There was immediate relief of both back and leg pain.

**Case 2** A 54-year-old retired business man was seen on July 12, 1938, with a complaint of pain in the small of the back of 4 years' duration. The pain had developed after a long automobile ride and was localized in the lumbo-

sacral region At the time of onset, the patient had been unable to move and had had to remain in bed for a week. He had not recovered completely from this acute attack, and in spite of heat, massage, exercise, chiropractic manipulation and a sacroiliac belt the pain had remained, but it did not incapacitate him.

Examination showed a well-developed and nourished man in no acute distress On standing, his back showed a marked left scoliosis The lumbosacral joint and the left posterior superior iliac spine were tender The back motions were good The hip motions were normal, except that rocking the pelvis with the knees flexed caused pain. The tensors were contracted. The patient was advised to wear a lumbosacral corset, sleep on a board and have baking and massage twice a week.

He showed no improvement under this regime. On September 15 the right thigh was strapped with adhesive tape. The patient "felt better immediately" The strapping was removed after 4 days The right knee could then touch the table in the Ober test, while the left lacked this ability by 8 cm The left thigh was strapped with adhesive tape. Five days later the tape was removed and the patient was given exercises for stretching the tensor fasciae latae muscle. Examination showed both tensors to be relaxed. The patient was again seen on October 11, when he felt '80 or 85 per cent better' He had some residual pain in his back, but he said that it was less intense and that it did not bother him

**Case 3** An 18-year-old nurse complained on November 1, 1938, of moderate backache and severe pain in the lateral aspect of the left thigh of 2 days duration. The evening before the onset of the pain she had slipped and fallen down six steps The pain was so severe that she limped Examination showed localized tenderness over the lateral aspect of the left mid thigh An x ray of the left hip and upper four fifths of the femur was normal The patient was seen 2 days later, still complaining of pain in the small of the back and severe pain in the lateral aspect of the thigh The lumbosacral and left sacroiliac regions were tender There was no restriction of back motion The straight leg-raising test was normal on the right, but was limited to 45° on the left. It was thought that the thigh pain was due to back strain Consequently an ordinary adhesive strapping was applied to the back.

The patient returned on November 10 The back strapping had relieved her backache, but had failed to alleviate the pain in the left thigh Examination showed a well-developed and nourished young woman with good posture. She walked with a left limp Palpation of the back was negative Motions of the back in the standing position were normal The hip motions were as follows

	RIGHT	LEFT
Straight leg raising	80°	50° with pain
Flexion	135°	135°
Rotation in flexion		
Internal	30°	30°
External	40°	40°
Ober test	22.5 cm	11.3 cm

The knee and ankle jerks were present and equal

A diagnosis was made of contracted fascia lata, worse on the right side. Although the pain was on the left side, the right thigh and lower back were strapped with adhesive tape in the manner described There was immediate relief of pain in the left thigh and the patient was able to walk without difficulty

The patient was seen again 12 days after strapping She had been free from pain except for 'occasional twinges' in the left thigh The motions of the back and the hip motions were normal The Ober and Ely tests were

negative. The strapping was removed and the patient given exercises to stretch the fascia.

The patient was seen 1 week later, or 19 days after application of the strapping She had no pain. The hip and back motions were normal The Ober and Ely tests were negative.

**Case 4** A 36-year-old housewife was seen November 17, 1938, complaining of severe pain in both sacroiliac regions of 3 days' duration The pain was worse on the left side. There was no radiation of pain down the leg and no increase of pain on sneezing or coughing Renal calculi had been removed 6 years previously and uncomplicated syphilis had been treated for the previous 6 years Wassermann tests had been negative for the previous 21 months. The patient's physician had strapped her back with adhesive tape, but without relief.

Examination showed a well-developed and nourished woman in acute distress, walking with a left limp and a list to the left. There was a right total scoliosis. Forward flexion of the spine in the standing position was markedly limited Palpation of the back showed tenderness over both posterior superior iliac spines with more tenderness on the left. Hip motions were as follows

	RIGHT	LEFT
Straight leg raising	70° with pain	70° with pain
Flexion	130° with pain	130° with pain
Rotation in flexion		
Internal	30°	30°
External	45°	45°
Ober test	10.0 cm	22.5 cm.
Ely test	13.8 cm.	18.8 cm.

The knee and ankle jerks were active and equal The legs were of equal length

A diagnosis was made of contracted fascia lata on the left due to spasm of the tensor fasciae latae and gluteus maximus muscles Roentgenograms were taken of the lower dorsal and lumbar spine and sacroiliac joints. They revealed a list to the left and right dorsolumbar scoliosis. Adhesive strapping was then applied to the left thigh and back. There was immediate and complete relief of pain. The patient was able to stand straight, walk and run without a limp X rays taken after strapping showed disappearance of the list and diminution of the scoliosis.

The patient was seen 2 days later She had no pain in the back During the preceding day only 'slight stiffness or soreness' in the small of the back had been present. Under the Ober test the knees touched the table without effort or pain The heels lacked 2 cm. of touching the buttocks in the Ely test. The patient was seen again 5 days after strapping She had no back pain, and examination of the back was negative. Three days later, or 8 days after strapping, the adhesive tape was removed. The patient had no back pain Examination of the back was normal and the Ober and Ely tests were negative.

## DISCUSSION

The fact that back strain with sciatica may, in some cases, be cured by heat and massage, leg traction or manipulation seems to point to localized muscle spasm as the underlying lesion in these patients Frequently at the onset of pain a "give" or "snap" is felt which is in accord with these considerations The relation of the tensor fasciae latae to back strain with sciatica was first pointed out by Ober<sup>1</sup> in 1935 In 1937 he reported 75 per cent of complete cures by fasciotomy of the fascia lata and proposed two explanations for these re

sults the contracted fascia lata exerts an abnormal pull on the pelvic bones and so causes a mechanical distortion of the spine, resulting in pain, or the pain may be due to spasm of the muscles about the posterior aspect of the hip joint. Freiberg, in 1934<sup>5</sup> and again in 1937,<sup>6</sup> discussed the relation of the piriformis muscle to sciatica and reported his operation for cutting the muscle. He found that in about 10 per cent of cadavers the sciatic nerve or its peroneal component pierced the muscle, and even when the nerve did not pass through the muscle, it lay in the great sciatic notch where spasm of the muscle could cause compression. Hence there is evidence that increased tension of the tensor fasciae latae, gluteus maximus and piriformis muscles may be etiologic factors in the causation of back symptoms or leg pain. It is also possible that pain along the distribution of the superior and inferior gluteal nerves may be related to muscle spasm. Since the action of the tensor fasciae latae is to abduct and flex, and that of the gluteus maximus and piriformis muscles to rotate the leg externally, the position of abduction, flexion and external rotation was chosen for strapping. The anterior portion of the adhesive strapping relieves the strain on the tensor fasciae latae, the posterior portion that on the gluteus maximus, and the position of external rotation supports the gluteus maximus and piriformis muscles.

The many causes of back pain, such as ruptured intervertebral disk, sacroiliac joint changes, disease of the spinal cord and pelvic disease,

are beyond the scope of this paper, since the method of treatment here presented is not designed for patients with such conditions. In conclusion, it is believed that this method may prove to be an addition to our conservative therapy, and that further application in a larger series of cases is desirable in order to evaluate its possible usefulness.

#### SUMMARY

A new, simple method of strapping for back strain with sciatica is presented, particularly for cases with contracted fascia lata or pain on internal rotation of the leg in the prone position.

The thigh and back are strapped with adhesive tape in such a manner as to relieve strain on the tensor fasciae latae, the gluteus maximus and the piriformis muscles.

The treatment is based on the assumption that back pain with sciatica may in some cases be due to localized muscle spasm, which either disturbs the mechanics of the spine or directly irritates the sciatic or gluteal nerves.

# MASSACHUSETTS MEDICAL SOCIETY

## PROCEEDINGS OF THE COUNCIL

STATED MEETING, FEBRUARY 1, 1939

A STATED meeting of the Council of the Massachusetts Medical Society was held in John Ware Hall, Boston Medical Library, 8 Fenway, Boston, on Wednesday, February 1. The president, Dr Channing Frothingham, Suffolk, was in the chair, and 192 councilors were present (Appendix No 1)

The record of the meeting of the Council, held on October 5, 1938, was presented as published in the *New England Journal of Medicine*, issue of November 10, 1938, and was declared approved as published

The President read the following obituaries

DR ALFRED A WHEELER, of Leominster, died July 22, 1938,\* in his sixty-eighth year

Born at Claremont, New Hampshire, he graduated from Harvard University and received his degree from the Harvard Medical School in 1894. He was district physician at the Boston Dispensary and admitting physician to the Out Patient Department of the Massachusetts General Hospital in 1895. From 1900 to 1906 he was surgeon to the Boston Dispensary.

Dr Wheeler was a fellow of the American Medical Association, and was a councilor and supervising censor from the Worcester North District at the time of his death.

His widow and four children survive him.

DR. MAX STURNICK, of 12 Columbia Road, Dorchester, died during the late fall of 1938. He was in his sixty second year.

Dr Sturnick received his degree from the Harvard Medical School in 1904. Since graduation as a house officer from the Boston City Hospital he had practiced medicine successfully in Dorchester. He was a member of the American Medical Association. At the time of his death he was a councilor of the Massachusetts Medical Society from the Norfolk District.

His widow survives him.

The Council stood for a period of silence out of respect to the memory of these councilors.

The report of the Auditing Committee was presented by the Treasurer (Appendix No 2). It was voted to accept the report as presented.

The report of the Treasurer (Appendix No 3) was presented by him and was duly accepted by the Council with applause. The Treasurer's report contained the recommendation that he be authorized to charge off or reduce the book value of two securities which had been carried on the books at their cost price. These securities are in the Build-

ing Fund and involve an issue of the Conveyancers Title Insurance and Mortgage Company guaranteed  $4\frac{1}{2}$  per cent bonds and an issue of Chicago, Rock Island and Pacific Railway first mortgage 4 per cent bonds due in 1934. The reason for the motion was to enable the Treasurer to present a truer picture of the actual assets of the Society. The motion was duly seconded and was carried. The Treasurer's suggestion concerning an honorarium for the Orator was referred to the Committee on Financial Planning and Budget.

### REPORTS OF STANDING COMMITTEES

#### *Financial Planning and Budget*

As this was the first report of a new committee, the chairman, Dr John Homans, Suffolk, stated that it was the committee's intention to proceed slowly and to gain familiarity with the work of the various committees and the necessity for expenditures by each. He said that the committee believes that the Society's external relations should be encouraged in every way, for example matters dealing with the government's interest in public health and its increasing invasion of the field of medicine, also matters dealing with the instruction of the profession. Other committees had been encouraged to express their views and certain problems such as those of the *Journal* had been discussed with the committee. The Council voted to accept the report. Dr Homans next presented the budget which had been prepared for the coming year and copies of which had been placed in the hands of the councilors (Appendix No 4).

Dr Edward Mellus, Middlesex South, moved that the item "returns to district societies" be increased to \$5000 since in his opinion the life of the Society is dependent on the activities of the district societies, and the recent reduction in this item has undoubtedly influenced these local activities. He pointed out the burden which had been placed on the district societies by the Council's decision to conduct the survey on the adequacy of medical care for the American Medical Association and to place the responsibility for this survey in the hands of the district societies. In some districts an extra two-dollar assessment had been necessary. He believed that the principle of extra assessments is very obnoxious to members of the district societies and seriously interferes with attendance and

\*Notice of death received after the meeting of the Council on October 5 1938

enthusiasm. He pointed out the saving that had been made by changing the publication of the *Directory* from an annual to a biennial basis. In his opinion some of this saving should be returned to the district societies. This motion was duly seconded.

During the discussion the treasurer, Dr. Charles S. Butler, Suffolk, showed that the excess of income over expenditures for the present year was in no small part due to a profit made from the sale of securities and, in his opinion, an increase in the amount returned to the district societies would be unwise.

Dr. Mellus insisted that the Society is constantly growing and that it needed the best it could get from the district societies. He suggested that there were many little ways in which the Society could economize, such as in the amount of material mailed by certain committees.

Dr. Homans felt called upon to defend the action of his committee in presenting the budget. He stated that this refund to the district societies belonged in the category of matters of internal administration and as such was one of the items on which the Society might economize. However, it appeared that this item was essential to keeping the Society active and the members interested. In his opinion, the refund was not a particularly good way of co-operating with the district societies but he would rather see this amount raised and the money expended whenever the district societies needed more money to keep them going at their most active and useful pace. When the vote was taken, it was found necessary to make a count. There were forty-four in favor of the motion and fifty opposed. The chair ruled that the motion was lost. It was then voted to adopt the budget as presented by the committee.

### *Membership*

The chairman, Dr. H. Quimby Gallupe, Middlesex South, presented the report of the committee which recommended that seventeen fellows be allowed to retire, four allowed to have their dues remitted, twenty-five allowed to resign, thirty-nine be deprived of the privileges of fellowship and one allowed to change his district without change of legal residence (Appendix No. 5). The Council adopted the report and approved the recommendations.

### *Arrangements*

The report was presented by the chairman, Dr. Richard P. Stetson, Norfolk (Appendix No. 6). This report contained the announcement that the one hundred and fifty-eighth annual meeting of the Society would be held in Worcester on June 6, 7 and 8, 1939. The report was accepted. The

committee recommended an allotment of an item of \$1500 for the expense of the committee, and since this was included in the budget adopted, the chair ruled that no separate action was needed.

### *Ethics and Discipline*

The report was presented by the chairman, Dr. Robert DeNormandie, Suffolk (Appendix No. 7). The report was duly accepted.

### *Medical Education and Medical Diplomas*

The chairman, Dr. Reginald Fitz, Suffolk, stated that the committee requested the various members of the Council to ask as many members as possible in their district societies to help the work of the committee by sending in to it confidential communications regarding the fitness of candidates for admission to the Society. He pointed out that the list of new candidates is published in the *New England Journal of Medicine* prior to the censors' meetings. The work of the committee would be greatly helped if such confidential information could be obtained so that better discrimination might be made in the acceptance of diplomas. The Council voted to accept the report.

### *State and National Legislation*

The report was presented by the chairman, Dr. Charles C. Lund, Suffolk. He called attention to a mimeographed report which had already been sent to the various members of the Council and members of the district legislative committees, which contained a great deal of information about each of the legislative bills so far studied by the committee. He called attention to the new regulations of the State Department of Public Health concerning blood transfusions. These regulations have served to obviate the necessity for the introduction of legislation in this matter. He reported that no bill concerning premarital examinations for protection against syphilis had met the approval of the committee which, however, does not believe it impossible to write such a bill. He said that the Massachusetts Society of Social Hygiene was attempting to do this.

At the time of issuing the preliminary report to the councilors, the committee was not aware of any bills having to do with health insurance. Since that time, however, a new bill, containing forty-three pages of single-spaced typewritten material, had been introduced by one of the labor organizations. He said that it is not the old bill which has so frequently been presented and that its provisions are so broad and the implications so extensive that the committee would need to devote a great amount of study to it. It would appear, however, that it contains many objectionable features.

Dr Lund stated that there was still disagreement as to the constitutionality of any proposal which would prevent the licensing of aliens and it was not known if such a bill would be introduced in the present session. There was one, however, which would forbid the issuing of licenses until the applicant had taken out first papers for citizenship. The committee had not yet studied this bill. He reported that a recess commission had been studying bills to establish separate boards of licensure in osteopathy and chiropractic. This report was thoroughly discussed in the communication sent to the councilors. So far nothing new had developed. He reported that there would be a hearing on February 2 on the bill to license hospitals, nursing homes and convalescent homes. He said that the nurses' reorganization bill is still in an unsatisfactory state and that, at the present time, no definite stand could be recommended.

He reported that the committee was divided in the matter of annual registration. Three members of the committee and the President favored the bill and two members opposed it. He explained the confusion which had occurred in connection with the hearing. He had been informed by a member of the committee that there would be a postponement until after the Council meeting, but a hearing was held as scheduled with a number of physicians appearing in opposition. The osteopathic physicians were quite fully represented in opposition. Dr Stephen Rushmore appeared in favor of the bill as did a few others. He called attention to the legislative bulletin which listed the bills that had been studied up to February 1 and which indicated those that the committee favored, those to which it was opposed and those on which a stand had not yet been taken.

After some discussion Dr David L. Lionberger, Norfolk, a member of the committee, was permitted to read a minority report from the committee which stated that the minority approved of the stand indicated in the legislative bulletin with certain exceptions, the chief one of which was in regard to annual registration. The minority recommended opposition to House Bill 60, which provides for annual registration of physicians, giving as its reasons that the Board of Registration in Medicine already had sufficient powers to correct the evils toward which the proposed bill was directed. He pointed out that the provisions of the present law direct the Board to investigate all complaints of violation of the act and to report these to the proper prosecuting officers. The minority believed that the matter of financing such prosecutions was one which concerned the Board and not the medical profession.

He pointed out that the expenses of the Board over a period of years had been much less than the amount of the fees received. The minority believed that such a bill would lead to further regimentation. The minority did not believe that the profession should be asked to purchase political favor by a provision which would merely insure additional income to the State. The Council voted to accept the minority report.

There was still further discussion as to the parliamentary procedure in handling the two reports. The chair ruled that both reports had been accepted by the Council. Both Dr Lionberger and Dr Lund rose to a point of order. The chair asked for a rising vote to sustain his ruling and it was found that this ruling was sustained by the Council.

Dr Lund then moved that the Council go on record as supporting the recommendations of the Committee on State and National Legislation as shown in the legislative bulletin of February 1, with the exception of House Bill 60 (annual registration). The motion was seconded and was carried after some discussion. It was pointed out that the matter of the attitude of the Council toward House Bill 60 was still in question and would need to be voted upon.

Dr Lund then moved that the privileges of the floor be extended to Dr Francis R. Mahony, of Lowell, chairman of the Board of Registration in Medicine. This motion was duly seconded and passed. Dr Lund then moved that the Council record itself in favor of the annual registration of physicians as provided in House Bill 60. This was duly seconded.

In the discussion which followed Dr David Cheever, Suffolk, asked that Dr Mahony be requested to make a statement defining the attitude of the Board of Registration in Medicine and Dr Mahony was asked by the President to come forward.

Dr Charles E. Mongan, Middlesex South, asked for information. He desired to know if the guest proposed to discuss the bill or was he simply present to answer questions asked by members of the Council. He stated that if Dr Mahony were to discuss the bill he would object since Dr Mahony was not a member of the Council. It was finally asked to have the stenographer read Dr Lund's motion verbatim. This motion was as follows:

I now move that the privileges of the floor be extended to Dr Francis Mahony, of Lowell, chairman of the Board of Registration in Medicine, who has come here to answer questions any members of the Council wish to ask him.

Dr Mongan then pointed out that the vote did not provide for a statement by Dr Mahony.

Dr Robert B Osgood, Suffolk, said that the Council wanted information and that, while Dr Mongan might be technically right, the obtaining of information was the important thing and that this was the spirit of the Council's vote. There was still further discussion.

Dr Cheever was finally permitted to ask Dr Mahony to state why he was in favor of annual registration.

After still further discussion Dr Mahony spoke to the Council stating that he was happy to have the privilege of appearing chiefly because it demonstrated that there was a spirit of co-operation between the legislative committee of the Society and the Board of Registration in Medicine. In answering Dr Cheever's question he felt that he would also be answering that of Dr Mongan. He stated that at first he was opposed to annual registration but, upon considering carefully the object of the bill which is not to protect licensed physicians from illegal competition but really to protect the public, even though it places a burden upon the medical profession, he believed that it should be supported. He stated that he realized the nuisance which it would create but, since the practice of medicine is of such vital importance to the interest of the State, steps should be taken to protect the public from quacks and charlatans who are practicing without license. He said that it was true that the Board had a record of the first registration of every license, but the Board had been in existence for a long time and consequently the records are not conclusive; men who had been licensed might have left the State or be dead. He stated that there have been instances of men practicing with licenses of deceased physicians. In his opinion the only way in which the problem could be met was by having annual registration. He pointed out that the objectionable features had been eliminated from the bill. He said that the questions to be answered are not difficult and, while the fee of two dollars must necessarily go into the general funds, it can come back to the Board by way of annual appropriations. He called attention to the economy which was forced on the Board and the limitations which were placed on its expenditures. He pointed out the duties of the inspectors which it is contemplated to engage. These men would obtain evidence of illegal practice of which there appears to be a considerable amount. He recalled that at one legislative hearing an unlicensed practitioner boasted that there were approximately three hundred practitioners of his cult in the State. He discussed the penalty clause of the bill which does not appear to be excessive. He stated that neglect to register would not destroy

the license to practice since a license once issued was good until revoked by the Board, but that annual registration of such license was necessary under the provisions of the bill.

Questions were asked by Dr Solomon Schwager, Berkshire, Dr Brainard F Conley, Middlesex South, Dr William H Robey, Suffolk, Dr Kenneth L MacLachlan, Middlesex East, Dr J Harper Blaisdell, Middlesex East, Dr Osgood, Dr Edward F Timmins, Suffolk, Dr Richard Dutton, Middlesex East, and two other councilors whose names were not given.

In reply to certain of these questions, Dr Mahony stated that we are being fully taxed at the present time. This is another form of indirect taxation. It was apparent to him that there is some suspicion that the Board of Registration in Medicine is antagonistic to the Society, but while he has been a member of the Board, he has found this to be untrue. He said that the members are physicians and some of them are former members of the Society. He stated that when they act they must consider questions of principle and that the opinions of the members of the Board were usually those of the Council. In his opinion, the annual registration of physicians should be given a trial. In his opinion this bill would aid in apprehending individuals who are illegally registered or who are practicing without a license. He said it would allow the employment of two inspectors whose duty would be to produce evidence of illegal practice. He pointed out that at present the Board is dependent on the State Police, an extremely busy body of men and that there is always delay and the condition is not satisfactory. In his opinion such a bill would protect the public by the elimination of the illegal practitioner. He stated that evidence of illegal practice, which was referred to by one of the questioners, was already under investigation by the State Police. Dr Mahony added that a bill was to be introduced which would eliminate the present unfortunate condition which allows only three members of the Massachusetts Medical Society to serve as members of the Board. He stated that eighteen other states have annual registration and are satisfied with it. He was not able to answer the question as to how successful the annual registration of dentists had been in Massachusetts.

Dr Conley pointed out that communications had been received from the profession in fourteen of the eighteen states referred to by Dr Mahony and that an opposite view was indicated since the money provided by the annual registration had not been utilized for the purpose intended.

Dr Mahony stated in answer to Dr Dutton's

question that he did not know of any co-operation between town clerks and the Board with regard to the registration of licenses

Dr Lund was not in agreement with Dr Conley on the interpretation of the opinions received from the profession in other states. He said that in certain cases at least the profession was satisfied that there was an improvement in conditions. In his opinion the law would do a minimum of harm and create a minimum of nuisance, and it would give the Board funds with which to work.

The matter was finally put to a vote and it was found that the Council approved of the majority report from the Committee on State and National Legislation to support House Bill 60 for the annual registration of physicians. When this vote was questioned a count was made: 114 were in favor and 34 opposed.

In connection with the bills on which the stand was undetermined Dr Lund reported that further study was necessary. In connection with House Bill 73, which provides for a supplementary report of congenital deformities, the Council voted to support the bill provided the language be altered to the satisfaction of the committee. House Bill 1407 proposes to prohibit aliens from practicing medicine by forbidding the Board to examine an applicant until he has taken out his first papers. It was voted to instruct the committee to favor the bill, with the inclusion of a provision for revocation of license in case the applicant fails to become a citizen within a reasonable time.

The President asked if there was any additional material to be presented by the minority and Dr Conley explained that Dr Lionberger had been called away in an emergency but that he (Dr Conley) would be glad to continue the minority report if it was so desired. After some discussion the chair ruled that the Council had acted on the minority report and had voted on all the bills that the committee had considered. The chair stated that if, however, there was any specific motion in connection with the minority report, he should be glad to entertain it. After considerable discussion as to how further action could be obtained on the minority report, it was finally decided that the Council had already voted confirming the attitude of the Committee on State and National Legislation as presented in the legislative bulletin and that, since it had acted specifically in the case of House Bill 60 (annual registration) and since there was no proposal directly before the Council to amend this action, the Council would proceed with the regular order of business.

## *Publications*

The chairman, Dr Roger I Lee, Suffolk, reported that his committee had chosen the Shattuck Lecturer for the annual meeting and that the Secretary would make this report to the Council. The Secretary later announced that the person chosen was Dr Wilder Penfield, of Montreal.

## *Public Health*

The report was presented by the chairman, Dr Osgood (See Appendix No 8). Dr Osgood in addition to the remarks contained in his formal report stated that the committee was very anxious to have the co-operation and criticism of the Society and would appreciate receiving comment favorable or unfavorable concerning its activities. He referred informally to several matters which had come to the attention of the committee but which were not considered of sufficient importance to be included in the report. The Council voted to accept the report.

## *Permanent Home*

The report was read by the chairman, Dr Robey (Appendix No 9). The Council voted to accept the report.

## REPORTS OF SPECIAL COMMITTEES

### *Cancer*

The report was presented by the chairman, Dr Shields Warren, Suffolk (Appendix No 10). It was accepted by the Council.

### *Postgraduate Instruction*

The chairman, Dr Frank R Ober, Suffolk, presented the report which was duly accepted (Appendix No 11). The following recommendations of the committee were duly presented and approved by the Council:

- 1 That the committee be instructed to present a postgraduate assembly next fall, and that the other New England state medical societies be invited to co-operate in sponsoring such an assembly if they so desire.
- 2 That the postgraduate extension courses and the teaching clinics be continued in co-operation with the government agencies, as has been done in the past.
- 3 That the chairman or secretary of the committee be instructed to attend the official meetings of the Associated Postgraduate Committees.

Dr Ober informed the Council that he intended to go to the meeting of the Associated Postgraduate Committees and that there would be no expense to the Society should he carry out his plans. Upon motion of Dr Osgood, duly seconded, it was voted that the appreciative thanks of the

Massachusetts Medical Society be extended to Harvard University for allowing the use of Sanders Theater to the delegates at the New England Postgraduate Assembly. The President pointed out that he appreciated this action of the Council because he had already expressed to the Corporation the thanks of the Society.

#### *Public Relations*

The report was presented by the secretary, Dr Elmer S. Bagnall, Essex North, and was accepted (Appendix No. 12).

Dr Hilbert F. Day, Middlesex South, asked if the activities of the committee would be hampered by the cut which had been made in the committee's appropriation. The President stated that the cut was made because the committee had not expended its full appropriation and that, with the introduction of economies, a larger appropriation would not be necessary, in his opinion.

Dr Alexander A. Levi, Middlesex South, asked that the letter describing the work done on the Ward Plan of the hospital insurance scheme in Lowell be read to the Council. He also asked if the committee had been consulted about certain changes in the details of the service furnished by the Associated Hospital Service Corporation, particularly with reference to anesthesia. The President replied that these changes had been discussed by the committee and that any prepayment plan for physicians' services would also be discussed.

Dr Michael A. Tighe, Middlesex North, was then asked to read the report of the Lowell arrangements (Appendix No. 13).

After Dr Bagnall read the recommendation contained in paragraph B of the committee's report, Dr Leon A. Alley, Plymouth, offered an amendment.

The President explained, in answer to questions, that at present the Associated Hospital Service Corporation insured only the patient's hospital bill and that the proposal to insure payment of doctors' fees by that organization would be limited to those policyholders who were receiving hospital benefits. The President also pointed out that the Associated Hospital Service Corporation is in a proper position to bring out an insurance scheme with or without co-operation from physicians but that it does not wish to do so. The matter was introduced to obtain an expression of opinion as to whether voluntary schemes should be handled by the Committee on Public Relations or should be referred back to the Council. In his opinion, delay in these matters might expedite the onset of compulsory sickness insurance.

Dr Lund expressed the opinion that the work

of his committee, in opposing a compulsory insurance bill now before the Legislature, would be strengthened if his committee could be assured that there was an arrangement in the Society which would allow such matters to be handled with expedition. He strongly favored the original motion.

Dr Levi asked for information concerning certain matters which had been referred to his district for a vote. He said that these matters had to do with the appointment of members of that district to represent it in the formation of the charter of the Associated Hospital Service Corporation, and that later the district was asked to have two members chosen to vote on changes which had been proposed.

Dr Blaisdell pointed out that the large directorate of the Associated Hospital Service Corporation is made up of delegates from various agencies, including medical societies, charitable groups, and so forth, and that a meeting is held annually for the purpose of going over important matters.

Dr Tighe expressed the opinion that the Council did not desire to give a subordinate committee the power which was implied in the original recommendation. In his opinion the Council should continue to reserve to itself the right of placing final approval or disapproval on any matter which is clearly of interest to a large number of its fellows. He expressed himself as favoring the amendment and opposing the original recommendation.

After some further discussion, the original motion with the amendment was duly passed. This action provided that, since the Committee on Public Relations had considered in principle a plan contemplated by the Associated Hospital Service Corporation for insurance to cover physicians' charges coincident with simultaneous insured hospitalization, the Council of the Massachusetts Medical Society approved in a general way of the suggestion and referred the matter back to the committee for detailed study, it being the understanding that the Council reserves the right of final action on any plan or plans which may result from these studies.

The Council recessed for the Cotung Luncheon.

Dr Bagnall read paragraph C of the committee's report which approved of the plans offered by the Farm Security Administration to provide loans to farmers for payment of doctors' bills. There was adverse discussion by Dr Francis P. McCarthy, Norfolk, Dr Edward A. Adams, Worcester North, and Dr John P. Monks, Suffolk, and favorable comment by Dr Ernest L. Hunt, Worcester. Upon a vote it was discovered that the recommendation of the committee was lost.

Dr Bagnall next presented the following

On recommendation of the American Medical Association that we establish in Massachusetts a Committee on Industrial Health, we recommend that the President be authorized to establish such a special committee to proceed at once to study the problems in this field in Massachusetts

The Council voted to approve this recommendation

Dr Frederick W O'Brien, Suffolk, presented a communication which had already been sent to the Committee on Public Relations (Appendix No 14) The President stated that, in his opinion, the matter in Dr O'Brien's communication is of vital importance and that it is at present under consideration by the committee He recalled that the Society had instructed the committee to bring various groups representing organized medicine into conference with groups representing organized hospital service He pointed out that a subcommittee, under the chairmanship of Dr Francis H Dunbar, had been bringing these groups together in the hope that some conclusion could be reached He said that it is the desire of the Associated Hospital Service Corporation that the doctors and the hospitals reach a satisfactory agreement so that the policies issued by the corporation may fit whatever plan the hospitals and the doctors propose

Dr John M Fallon, Worcester, presented a communication from the New England Society of Anesthesiology (Appendix No 15) The President stated that this was more evidence showing the necessity for the doctors and hospitals to reach an agreement in these matters of special service He stated that the Associated Hospital Service Corporation is interested in seeing that there is no discrimination against its subscribers, who, it believes, should receive the same treatment from the hospital as the hospital gives to other individuals who have the same type of hospital accommodations and for which they pay the hospital directly The President answered a question from Dr Maclachlan stating that *at present the sum of five dollars is allotted* to the hospital by the corporation when anesthesia is given by a salaried employee of the hospital or a house officer, otherwise the hospital gets nothing

#### Miscellaneous

The President read the names of five fellows whose applications for restoration to fellowship had been studied by regularly appointed committees and whose restoration was recommended (Appendix No 16) The Council voted to confirm the recommendations in these cases

The President stated that the committee appointed to consider the name of Dr Hyman S

Queen, of New Bedford, recommended that he be not restored The Council voted to approve the recommendation

#### APPOINTMENT OF DELEGATES

The President presented nominations of the following to serve as delegates and alternates to the House of Delegates of the American Medical Association for two years beginning June 1, 1939

<i>Delegates</i>	<i>Alternates</i>
Edmond F Cody, Bristol South	Edward L. Merritt, Bristol South
John M Birnie, Hampden	Robert J Carpenter, Berkshire
Richard H. Miller, Suffolk	Cadis Phipps, Norfolk

There being no other nominations from the floor, it was moved and seconded that the nominations be closed and the Council voted to elect those named above

The President presented nominations of the following to serve as delegates to the annual meetings of the other state medical societies in New England

<i>Maine</i>	Frank W Snow, Essex North
	Charles F Warren, Essex North
<i>New Hampshire</i>	Edward A Adams, Worcester North
	Thomas R. Donovan, Worcester North
<i>Vermont</i>	Howard M Kemp, Franklin
	Modestino Criscitello, Jr, Berkshire
<i>Rhode Island</i>	George W Blood, Bristol South
	Harold E Perry, Bristol South
<i>Connecticut</i>	Theodore L. Story, Worcester
	William A R. Chapin, Hampden

Upon a motion, duly seconded, it was voted to approve the appointments

The President nominated Dr Alexander S Begg, Norfolk, as delegate to the Annual Congress on Medical Education and Licensure of the American Medical Association On motion, duly seconded, the selection was approved

#### APPOINTMENT OF COMMITTEES

The President proceeded to announce the list of those applying for restoration to fellowship and the names of the committees appointed to consider each case (Appendix No 17) The Council voted to approve the recommendations

The President nominated the following fellows to represent the Society on the Massachusetts Central Health Council

Robert J Carpenter, Berkshire  
George D Henderson, Hampden  
William D Kinney, Barnstable  
Erwin C Miller, Worcester  
Robert B Osgood, Suffolk  
Michael A Tighe, Middlesex North

The nominations were confirmed by vote and the appointments approved

#### INCIDENTAL BUSINESS

The Society voted to confirm the election to fellowship of John W Turner, of Westfield, whose name was received too late for publication in the *New England Journal of Medicine*, as required under the by-laws, and who was passed by the Board of Censors of Hampden District.

The President announced that the Council had ordered the publication of the by-laws as amended inasmuch as the amendments will result in certain minor changes in other parts of the by-laws, he proposed that a committee of three, plus the Secretary, be appointed for the purpose of editing the material before it is submitted to the printer. The Council voted to approve the appointment of this committee.

In order to facilitate the study of various plans proposed to assist individuals in the low-income class to obtain proper medical care, Dr Hunt introduced a resolution (Appendix No 18). After considerable discussion, which included some references to contract practice, the resolution was referred to the Committee on Public Relations.

The President announced that the physicians on Martha's Vineyard had requested an opportunity to present to the Council a statement of the situation in which they found themselves with regard to membership in their district society. Upon motion of Dr Tighe it was voted that unanimous consent be given to the representative from Martha's Vineyard to present a statement.

Dr Roswell H Smith, of Martha's Vineyard, stated that the physicians on the island are very anxious to have the benefit of the privileges accorded to fellows of the Society but, because of difficulties in transportation, it is impossible for these men to attend the meetings of the Bristol South District Medical Society at New Bedford or Fall River without the loss of an excessive amount of time. He pointed out that to attend such a meeting the physician must leave Martha's Vineyard by boat at six o'clock in the morning and, after a two and a half hour sail to New Bedford, must wait until the meeting is called, either at five in the afternoon or at eight o'clock at night. He said that it is then impossible for the member to return to the Vineyard on the same day and that as a result he must lose two days from his work in order to attend a society meeting. He illustrated the difficulty by pointing out that he had left Martha's Vineyard the preceding after-

noon at five o'clock and had arrived in Boston at nine in the evening and that, after attending the Council meeting and presenting his statement, it was impossible for him to return to the Vineyard until the next day, and only then provided the weather conditions were good. He said that the physicians in the Vineyard are very anxious to improve themselves in every possible way. He stated that after a long struggle they have succeeded in establishing a very good hospital, which operates the year round, and that they have organized themselves into the Martha's Vineyard Medical Society, with a membership of ten. He said that this Society meets each month and has had the pleasure of entertaining speakers from Boston and elsewhere and that the Massachusetts Medical Society had been helpful and co-operative in providing the assistance needed for the meetings. Since the group is interested in the work of the Society and is attempting to carry out its principles and precepts, he pointed out that it is desirous of being permitted to establish a separate district for this purpose.

In the discussion, the question was raised as to the situation on Nantucket. Dr Smith pointed out that Nantucket is in a separate county and that it is as difficult to get to Nantucket and back from the Vineyard as it is to get from Nantucket to Boston and return. The President recalled that a committee had previously been appointed to consider district boundaries. He said that Dr John M Burnie, Hampden, is chairman of this committee and suggested that the matter be referred to that committee for a report at the next meeting of the Council. The Council voted to approve.

Dr Henry M Landesman, Norfolk, stated that, under the operation of the "Gentleman's Agreement" the committee had had but eight complaints from physicians throughout the State and that these complaints had all been adjusted. He said that apparently the agreement is working satisfactorily. He reported that hospital officials have informed him that their difficulties over the collection of bills have been much reduced. Dr Landesman then spoke of two bills which had been introduced into the legislature by Representative Sirois, with reference to blood tests for syphilis. He stated that objections previously raised to certain provisions of the bill had been corrected and that he did not believe that the Society would be in opposition to them.

There being no further business to come before the Council, adjournment was declared at 3 15 p m.

Dr Bagnall next presented the following

On recommendation of the American Medical Association that we establish in Massachusetts a Committee on Industrial Health, we recommend that the President be authorized to establish such a special committee to proceed at once to study the problems in this field in Massachusetts

The Council voted to approve this recommendation

Dr Frederick W O'Brien, Suffolk, presented a communication which had already been sent to the Committee on Public Relations (Appendix No 14) The President stated that, in his opinion, the matter in Dr O'Brien's communication is of vital importance and that it is at present under consideration by the committee He recalled that the Society had instructed the committee to bring various groups representing organized medicine into conference with groups representing organized hospital service He pointed out that a subcommittee, under the chairmanship of Dr Francis H Dunbar, had been bringing these groups together in the hope that some conclusion could be reached He said that it is the desire of the Associated Hospital Service Corporation that the doctors and the hospitals reach a satisfactory agreement so that the policies issued by the corporation may fit whatever plan the hospitals and the doctors propose

Dr John M Fallon, Worcester, presented a communication from the New England Society of Anesthesiology (Appendix No 15) The President stated that this was more evidence showing the necessity for the doctors and hospitals to reach an agreement in these matters of special service He stated that the Associated Hospital Service Corporation is interested in seeing that there is no discrimination against its subscribers, who, it believes, should receive the same treatment from the hospital as the hospital gives to other individuals who have the same type of hospital accommodations and for which they pay the hospital directly The President answered a question from Dr MacLachlan stating that *at present the sum of five dollars is allotted to the hospital by the corporation when anesthesia is given by a salaried employee of the hospital or a house officer, otherwise the hospital gets nothing*

The Auditing Committee  
Dr J B Thomes and Dr Augustus Thorndike, Jr  
The Massachusetts Medical Society  
Boston, Massachusetts

Gentlemen

At the request of your treasurer, Dr Charles S Butler,  
we have examined the books and accounts of the Massa-  
chusetts Medical Society for the twelve months ended  
December 31, 1938 and submit herewith

Schedule A Statement showing the balance sheet  
of the Massachusetts Medical Society,  
December 31, 1938

Schedule B Statement showing the revenue and  
expenses of the Massachusetts Medi-  
cal Society for the twelve months  
ended December 31, 1938

The cash on deposit in the banks has been reconciled  
with the bank statements and found correct.

The cash receipts as recorded have been properly ac-  
counted for and disbursements are supported by vouchers  
or canceled checks which were examined by us

The securities and savings bank books in the various  
funds were examined by us

The accompanying balance sheet and related statement  
of revenue and expenses fairly present its position at  
December 31, 1938 and results of its operations for the  
year

Respectfully submitted,  
HARTSHORN AND WALTER.

## APPENDIX NO 2

## REPORT OF THE AUDITING COMMITTEE

The Auditing Committee has received from the certified public accountants, Messrs Hartshorn and Walter, the audit of the books of the Treasurer, herewith submitted for 1938

The committee reports that the above mentioned certified public accountants examined the securities in the care of the Treasurer and found them present and correct.

JOHN B THOMES, *Chairman*,  
AUGUSTUS THORNDIKE, JR.

## APPENDIX NO 3

## REPORT OF THE TREASURER

The Treasurer has had the same difficult problem, the past year, as for the previous two or three years,—perhaps even more acutely in 1938,—namely investing and re-investing the available funds of the Society. Interest returns on prime bonds are now lower than ever, due in part to large inflow of gold and in part to measures by U S Treasury Department. U S Government short paper has recently sold at no interest return, and prime corporation bonds, with maturities within five to ten years, are selling to net from 1½ to 2% per cent. The Treasurer looks ahead with much doubt. One result of these conditions has been that the Treasurer has carried a larger cash balance than necessary and this, in consequence, has reduced the income return from our invested funds which the Society should have received. It should be emphasized again, however, that the revenue from annual dues of fellows has been, as usual, the main source of income making about 90 per cent of our total.

Revenues received, during 1938 from annual dues of resident fellows amount to \$48,290, showing a considerable increase over 1937. Adding to this the annual dues from non resident fellows of \$1 489 makes the total income from dues \$49 779 the largest amount from this source ever received by the Society. Other revenues—invested funds, \$3,919 22 proceeds of sales of publications \$58 54 and profits from sales of securities \$1,521 22—amount to \$5,498 98. Therefore the Society's total revenue in 1938, not including income from the Building

Fund, was \$55,277.98. This is, again, the largest total ever received by the Society.

The Building Fund had a net income in 1938 of \$1,673 46, this is less than in 1937. But the Treasurer is glad to report a small profit of \$249 79 from sales of securities and a generous gift of \$1,000 to this fund from a loyal friend. The fund now has a book value of over \$63,000. In the fund, there are two issues of bonds, each of \$5,000, now for years in default, and hence with greatly reduced market values. The Treasurer recommends, for a clearer statement of this fund, that he be authorized to charge off, or reduce, the book values of these two issues, to their approximate present values. This mark-off would amount to \$8,000 for the two issues—one issue \$3,500, the other \$4,500. If the Council approves this, then the statement of the fund will show more accurately its value.

Expenses of the Society during 1938 totaled \$50,653 74. The activities of several committees for the protection of the health of the people, and for the good of the fellows of the Society were greater than ever before. All of us benefit thereby. There are not many items which can at present be reduced without curtailing the duties of the Massachusetts Medical Society, both the public and to our fellows.

The Treasurer ventures to offer a suggestion to the Council, namely, would it be proper to give the Orator a modest honorarium for his oration, from which we derive so much benefit, at the annual meeting?

The Society ends 1938 with unexpended revenues of \$4,624.24. Total assets now amount to \$190,307.36, an increase for the year of over \$9,000.

The Treasurer takes this opportunity to thank the officers of the Society and the district officers for their co-operation, and, especially, to thank the members of the office staff of the *New England Journal of Medicine* for their helpfulness and assistance.

The Treasurer invites questions.

CHARLES S BUTLER, *Treasurer*

## APPENDIX NO 3

## REPORT OF THE TREASURER

The Treasurer has had the same difficult problem, the past year, as for the previous two or three years, — perhaps even more acutely in 1938, — namely investing and re-investing the available funds of the Society. Interest returns on prime bonds are now lower than ever, due in part to large inflow of gold and in part to measures by U S Treasury Department. U S Government short paper has recently sold at no interest return, and prime corporation bonds, with maturities within five to ten years, are selling to net from 1½ to 2½ per cent. The Treasurer looks ahead with much doubt. One result of these conditions has been that the Treasurer has carried a larger cash balance than necessary and this, in consequence, has reduced the income return from our invested funds which the Society should have received. It should be emphasized again, however, that the revenue from annual dues of fellows has been, as usual, the main source of income, making about 90 per cent of our total.

Revenues received, during 1938 from annual dues of resident fellows amount to \$48 290, showing a considerable increase over 1937. Adding to this the annual dues from non-resident fellows of \$1,489 makes the total income from dues \$49,779, the largest amount from this source ever received by the Society. Other revenues — invested funds, \$3,919 22 proceeds of sales of publications \$58 54 and profits from sales of securities \$1,521.22 — amount to \$5,498.98. Therefore the Society's total revenue in 1938, not including income from the Building

Fund, was \$55,277.98. This is, again, the largest total ever received by the Society.

The Building Fund had a net income in 1938 of \$1,673 46, this is less than in 1937. But the Treasurer is glad to report a small profit of \$249 79 from sales of securities and a generous gift of \$1,000 to this fund from a loyal friend. The fund now has a book value of over \$63,000. In the fund, there are two issues of bonds, each of \$5,000, now for years in default, and hence with greatly reduced market values. The Treasurer recommends, for a clearer statement of this fund, that he be authorized to charge off, or reduce, the book values of these two issues, to their approximate present values. This mark-off would amount to \$8,000 for the two issues — one issue \$3,500, the other \$4,500. If the Council approves this, then the statement of the fund will show more accurately its value.

Expenses of the Society during 1938 totaled \$50,653 74. The activities of several committees for the protection of the health of the people, and for the good of the fellows of the Society were greater than ever before. All of us benefit thereby. There are not many items which can at present be reduced without curtailing the duties of the Massachusetts Medical Society, both the public and to our fellows.

The Treasurer ventures to offer a suggestion to the Council, namely, would it be proper to give the Orator a modest honorarium for his oration, from which we derive so much benefit, at the annual meeting?

The Society ends 1938 with unexpended revenues of \$4,624.24. Total assets now amount to \$190,307 36, an increase for the year of over \$9,000.

The Treasurer takes this opportunity to thank the officers of the Society and the district officers for their co-operation, and, especially, to thank the members of the office staff of the *New England Journal of Medicine* for their helpfulness and assistance.

The Treasurer invites questions.

CHARLES S BUTLER, *Treasurer*

## APPENDIX NO 3

## REPORT OF THE TREASURER

The Treasurer has had the same difficult problem, the past year, as for the previous two or three years,—perhaps even more acutely in 1938,—namely investing and re-investing the available funds of the Society. Interest returns on prime bonds are now lower than ever, due in part to large inflow of gold and in part to measures by U S Treasury Department. U S Government short paper has recently sold at no interest return and prime corporation bonds, with maturities within five to ten years are selling to net from 1½ to 2½ per cent. The Treasurer looks ahead with much doubt. One result of these conditions has been that the Treasurer has carried a larger cash balance than necessary and this, in consequence, has reduced the income return from our invested funds which the Society should have received. It should be emphasized again, however, that the revenue from annual dues of fellows has been, as usual, the main source of income, making about 90 per cent of our total.

Revenues received, during 1938 from annual dues of resident fellows amount to \$48,290 showing a considerable increase over 1937. Adding to this the annual dues from non-resident fellows of \$1,489 makes the total income from dues \$49,779 the largest amount from this source ever received by the Society. Other revenues—invested funds, \$3,919 22 proceeds of sales of publications \$58 54 and profits from sales of securities \$1,521 22—amount to \$5,498 98. Therefore the Society's total revenue in 1938, not including income from the Building

Fund, was \$55,277 98. This is, again, the largest total ever received by the Society.

The Building Fund had a net income in 1938 of \$1,673 46, this is less than in 1937. But the Treasurer is glad to report a small profit of \$249 79 from sales of securities and a generous gift of \$1,000 to this fund from a loyal friend. The fund now has a book value of over \$63,000. In the fund, there are two issues of bonds, each of \$5,000, now for years in default, and hence with greatly reduced market values. The Treasurer recommends, for a clearer statement of this fund, that he be authorized to charge off, or reduce, the book values of these two issues, to their approximate present values. This mark-off would amount to \$8,000 for the two issues—one issue \$3,500, the other \$4,500. If the Council approves this, then the statement of the fund will show more accurately its value.

Expenses of the Society during 1938 totaled \$50,653 74. The activities of several committees for the protection of the health of the people, and for the good of the fellows of the Society were greater than ever before. All of us benefit thereby. There are not many items which can at present be reduced without curtailing the duties of the Massachusetts Medical Society, both the public and to our fellows.

The Treasurer ventures to offer a suggestion to the Council, namely, would it be proper to give the Orator a modest honorarium for his oration, from which we derive so much benefit, at the annual meeting?

The Society ends 1938 with unexpended revenues of \$4,624 24. Total assets now amount to \$190,307 36, an increase for the year of over \$9,000.

The Treasurer takes this opportunity to thank the officers of the Society and the district officers for their co-operation, and, especially, to thank the members of the office staff of the *New England Journal of Medicine* for their helpfulness and assistance.

The Treasurer invites questions.

CHARLES S BUTLER, *Treasurer*

### REPORT OF THE COMMITTEE ON MEMBERSHIP

This committee recommends

1 That the following named seventeen fellows be allowed to retire as of December 31, 1938, under the provisions of Chapter I, Section 5, of the by laws

Barrett, Edward W, Medford  
 Brousseau, William G, Cambridge  
 Fischbein, Louis, Allston  
 Haslam, Frank A, Brookline  
 Hurd, Randolph C, Newburyport  
 MacCarthy, Francis H, Gilford, New Hampshire, with remission of dues for 1938  
 Mahoney, John L, St. Petersburg, Florida, with remission of dues for 1938  
 McKibben, William W, Miami, Florida, with remission of dues for 1937 and 1938  
 O'Brien, John C, Greenfield  
 Pollard, John W H, Groveland  
 Schmidt, Richard D, Dorchester  
 Shattuck, Albert M, Worcester  
 Sherman, Frank M, West Newton  
 Sternberg, Joseph E, Dorchester, with remission of dues for 1937 and 1938  
 Walker, Lewis M, Cambridge  
 Williams, Edward D, Easthampton, with remission of dues for 1937 and 1938  
 Worthing, Frank B, Chatham, with remission of dues for 1936, 1937 and 1938

2. That the dues of the following named four fellows be remitted under the provisions of Chapter I, Section 6, of the by-laws

Bill, Jose P, Wayland, 1936, 1937 and 1938  
 Campbell, Franklin E, West Medford, 1939  
 Gibson, David H, Cambridge, 1936 1937 and 1938  
 Rumrill, Samuel D, Springfield, 1937 and 1938

3 That the following named twenty four fellows be allowed to resign as of December 31, 1938, under the provisions of Chapter I, Section 7, of the by laws

Bray, Walter A, North Stratford, New Hampshire  
 Bufford, John H, Newton Highlands  
 Cameron, Donald E, Albany, New York  
 Carrano, Armand T, New York City, with remission of dues for 1938  
 Clark, Anne L, New York City  
 Costa, Domizio A, Revere (a member of the Board of Registration in Medicine)

Curtis, Robert D, Manchester, Vermont  
 Dawson, Raymond J, Methuen  
 Dean, Stanley R, Newtown, Connecticut  
 Giannestras, Nicholas J, Cincinnati, Ohio, with remission of dues for 1937 and 1938  
 Gordon, George K, Malden  
 Hammond, John W, Jr, Riverdale-on Hudson, New York, with remission of dues for 1937 and 1938  
 Hershenson, Bert B, Brooklyn, New York  
 Ledger, George H, Union City, Pennsylvania, with remission of dues for 1937 and 1938  
 Machaj, Stanley W, Portsmouth, New Hampshire  
 Overholser, Winfred, Washington, District of Columbia  
 Simons, Donald J, New York City, with remission of dues for 1938  
 Smilie, Wilson G, New York City, with remission of dues for 1938  
 Stewart, Roger E, Seattle, Washington  
 Tanner, Walter L, Morristown, New Jersey  
 Tooker, Harold C, Bloomfield, New Jersey  
 Toppan, Roland L, Newburyport  
 Webb, Harold R, Brunswick, Maine  
 White, Lucy N, Pawlet, Vermont

4 That the following named fellow be allowed to resign as of December 31, 1938, under the provisions of Chapter VII, Section 4, of the by laws

Shulman, David H, Brookline

5 That the following named thirty nine fellows be deprived of the privileges of fellowship under the provisions of Chapter I, Section 8, Clauses a and b of the by laws

Baker, Harold W, Boston  
 Baker, Max, Newmarket, New Hampshire  
 Balser, Charles W, Detroit, Michigan  
 Barnes, Harry A, Dedham  
 Baxter, Alfred E, Lowell  
 Bianco, Harvey H, North Adams  
 Black, George L, Lawrence  
 Burckel, Arthur W, Adams  
 Cohen, Lionel, Holyoke  
 Cort, Parker M, Springfield  
 Costine, Robert A, North Adams  
 Craig, Henry R, Eloise, Michigan  
 Cunha, Felix, San Francisco, California  
 DeAsis, Cesaro, Cagayan, Philippine Islands  
 Donohue, Jeremiah J, Worcester  
 Ducey, William D, Brockton  
 Flynn, Joseph C, Providence, Rhode Island  
 Fox, Isadore, Boston  
 Harvey, Frank T, Milford  
 Hughes, George F, Somerville  
 Kasheta, Francis J, Warren, New Hampshire  
 Kelly, Daniel J, Adams  
 Kerkhoff, Edith, Attleboro  
 Kushner, Irving L, Somerville  
 Macnaughton, Elizabeth, Walpole, New Hampshire  
 McCartin, John E, Boston  
 Murray, George A, Dorchester  
 O'Brien, John F, Fall River  
 Peck, Eugene C, Leonardtown, Maryland  
 Pidgeon, Ira S, Waban  
 Pomerleau, Rodolphe J F, Augusta, Maine  
 Prenn, Joseph, Boston  
 Sherwood, Walter, Wellesley  
 Smith, Edward M, Exeter, New Hampshire  
 Sughrue, Dennis F, Dorchester  
 Sullivan, George M, Stoughton

Tait, Harold S, Palmer  
 Vuornos, Sirkka E., Liberty, New York  
 Wright, Katherine H. L., Erie, Pennsylvania

6 That the following named fellow be allowed to change his membership from one district society to another without change of legal residence, under the provisions of Chapter III, Section 3, of the by-laws

From Plymouth to Suffolk

Murphy, William F, Scituate Harbor

## APPENDIX NO 6

### REPORT OF THE COMMITTEE OF ARRANGEMENTS

Under the enthusiastic and able guidance of Dr Charles A. Sparrow, of Worcester, local committees have been appointed, and arrangements for the annual meeting are well under way

Due to certain expenses necessarily incurred in a meeting outside of Boston and to the fact that a rent of \$600 is being charged for use of the Worcester Auditorium the Committee of Arrangements respectfully requests the Council to approve its estimate of \$1500 for expenses of the committee in conjunction with the one hundred and fifty-eighth annual meeting of the Society to be held in Worcester, June 6, 7 and 8, 1939

RICHARD P STETSON, *Chairman*

## APPENDIX NO 7

### REPORT OF THE COMMITTEE ON ETHICS AND DISCIPLINE

Since our last report to the Council the committee has held three meetings. We have considered twenty complaints, requests for information or charges of unethical conduct of fellows. It was necessary to hold three hearings in order to come to a satisfactory understanding of the complaints, and we have heard the charges of unprofessional conduct from one layman against a fellow.

One hearing was given to a fellow whose registration to practice medicine had been revoked by the Board of Registration in Medicine because of very serious irregularities in the management of a pregnancy. The conflicting nature of the testimony made it improbable that a board of trial would lead to a successful termination, and as the fellow offered his resignation the committee accepted it.

The second hearing was to a fellow, a former treasurer of one of the district societies, for gross carelessness in the handling of the district's funds. The matter has now been straightened out. It was voted that it was the opinion of the committee that all district societies should have an auditing committee to audit the treasurer's accounts yearly, or whenever a change in office takes place.

The third hearing was given to a fellow who was interested in the manufacture and sale of a secret medicinal product. We have had much correspondence with him in regard to this matter and he has now agreed to give up the manufacture and all interest in the product.

Practically all the complaints resolve themselves around the desire of fellows to obtain a greater advantage over their confreres in some way or other. They have been adjusted either by interview with the chairman or by correspondence with the physicians in question. We have been governed in dealing with these cases by the state

ment regarding publicity which we gave to the Council a year ago

ROBERT L DeNORMANDIE, *Chairman*

## APPENDIX NO 8

### REPORT OF THE COMMITTEE ON PUBLIC HEALTH

The Committee on Public Health and its Subcommittee on Public Education beg leave to submit the following report.

The radio broadcasts apparently continue to be a useful method of public education. Following the October announcement in the *New England Journal of Medicine* and the daily press that the 'Green Lights to Health' would again be broadcast under the auspices of the State Department of Public Health and the Massachusetts Medical Society, the Subcommittee on Public Education received approximately two hundred requests from schools, associations, physicians and laymen for copies of the entire series. This unexpected demand forced the committee to exceed somewhat irregularly its appropriation because of the extra postage and stationery required to satisfy this demand. After explanation our efficient and kindly treasurer and his advisers found the means to meet these sudden and unexpected obligations.

The change of time of delivery of these broadcasts from 7:45 to 4:00 p.m., which the radio station found it necessary to impose, has given us a diminished radio audience, but in spite of this, fan mail continues to come in and indicates that so far, with only about half of our broadcasts delivered, we have reached about 130,000 people in addition to the two hundred and fifty copies of the broadcasts mailed by request each week. It is interesting to note the subjects which have aroused the greatest interest. The largest response in the way of fan mail thus far has come after the broadcasts on 'Having a Baby the Right Way' by Dr Roy J. Heffernan, 'What to Eat and Why' by Dr Sara M. Jordan, 'Diabetes' by Dr Albert A. Hornor, and what is most suggestive of all as indicating the consumers' interest in medical care, the excellent broadcast of Dr Michael A. Tighe on 'Community Health Councils'. A sensible means of improving the distribution of medical care. This would seem to emphasize the fact that it would be wise for the Massachusetts Medical Society and its county societies to bestir themselves in stimulating and in aiding and abetting the formation of such community councils.

The committee wishes to thank the members of the Council for a better response this year to the committee's request for criticism, favorable or otherwise, of the broadcasts. At the October, 1937, meeting of the Council we distributed fifty addressed postals to members who promised to listen in. The total response was four, or 8 per cent. At the October, 1938, meeting of the Council we distributed a hundred addressed postals. The response thus far has been sixteen, or 16 per cent—not a very generous response but twice as large as last year. I am glad to report that these responses have been almost unanimously favorable.

In November 1938, the Massachusetts Department of Public Health was approached by a representative of one of the Boston daily newspapers in relation to the publication in its columns of articles written by physicians on the various aspects of present-day medicine. The Department of Public Health graciously consulted the Committee on Public Health of the Massachusetts Medical Society

as to the propriety of such a pioneer venture. After a combined meeting of representatives of the Department of Public Health, the president of the Massachusetts Medical Society, representatives of the standing committees of the Massachusetts Medical Society on public relations, legislation, ethics and discipline, and public health, and representatives of the Massachusetts Dental Society, it was unanimously voted to approve in principle such an undertaking. The Department of Public Health and the Committee on Public Health of the Massachusetts Medical Society were asked to explore the matter further along the lines suggested and approved at this combined meeting. This exploration revealed the fact that the final authority of the paper whose representative had proposed the plan was unable or unwilling to publish the articles proposed in a manner which seemed to the Department of Public Health and to the Committee on Public Health of the Massachusetts Medical Society to be consistent with medical ethics. Before this became apparent it had been ascertained that the deans of the three important medical schools, the directors of the large hospitals and the full time teachers of medicine and surgery were in sympathy with the plan and were willing to prepare articles for such public consumption. The editors of the *Boston Evening Transcript* were then interviewed, and readily agreed to publish a series of some sixty such articles in consecutive issues of their paper and to safeguard fully the ethics of the profession.

The members of the Council have doubtless read the editorial in the *New England Journal of Medicine* of December 16, 1938. The articles which have been appearing daily in the *Transcript* under the title of "A Doctor a Day" since December 19 have been roughly grouped into four series. The first series deals with training of a physician from his premedical education until he becomes a general practitioner, a specialist or a public-health officer. In the second series the public is told of what goes on in modern hospitals and of their many and varied services to medicine and nursing. In the third series the Department of Public Health describes its multitudinous activities in safeguarding the health of the citizens and in making it easy for the physicians of the State to obtain the complicated biochemical products which have become necessary for adequate practice. The fourth series not yet published will discuss certain diseases for which specific or partially specific methods of treatment have been discovered.

This is, so far as we know, the first time that physicians in any organized manner have tried in their own words and at first hand to tell the public what they think the public wants to know and ought to know about the practical aspects of medicine.

The State Department of Public Health and the Committee on Public Health of the Massachusetts Medical Society will welcome the constructive criticism of the Council of this undertaking. It has been surprisingly easy to put through because of the *pro bono publico* spirit which is especially prevalent in this community among the medical profession. So far as we can remember not a single physician has refused to write a requested article after the purpose of the plan was explained.

Many requests have already been made by physicians and laymen for the reprinting of the whole series in inexpensive brochure form under some such title as *Modern Medicine in Massachusetts*. One leading physician in the western part of the State has offered to purchase two hundred copies of such a brochure for use in his own private practice. We hope to be able to arrange for such a publication. Members of the Council can help us greatly in

this endeavor if they will write letters to the editorial office of the *Boston Evening Transcript* urging that such a brochure be made available. It would be still more effective if you could induce any of your patients or lay friends who have read the articles to write letters of this sort. The committee urgently requests your co-operation.

ROBERT B. OSGOOD, *Chairman*,  
GERALD N. HOEFFEL, *Secretary*

## APPENDIX NO 9

### REPORT OF THE COMMITTEE ON PERMANENT HOME

The Committee on Permanent Home of the Massachusetts Medical Society makes the following report.

We are indebted to our competent treasurer, Dr. Charles S. Butler, for the following financial statement:

The Building Fund on December 31, 1938, had a book value of \$63,184.65. In the above amount are included income in 1938 from securities of \$1,673.46, a gift from a friend of \$1,000.00 and a profit from the sale of several securities of \$249.79, making a gain in the book value of the fund since 1937 of \$2,923.25.

On January 10, 1939, your committee held a meeting with all members present except Dr. Erwin C. Miller. It is our belief that the Society is financially able to purchase a suitable house, especially in the present state of the market, and would be able to furnish the building. On the other hand, unless it was adjacent to the medical library, its value to members would be considerably diminished. As a club it would have small use if we may judge from similar medical buildings in other cities. It would add to our comfort if we could have a large, well furnished hall and suitable committee rooms, but with our present arrangements in the library building we manage reasonably well, if not ideally. It is the opinion of your committee that it would be wise to defer action until some favorable opportunity presents itself.

WILLIAM H. ROBES, *Chairman*

## APPENDIX NO 10

### REPORT OF THE COMMITTEE ON CANCER

Through the recognition of the special interest of the Massachusetts Medical Society and the Massachusetts Department of Public Health in cancer education, a suitable program for co-operative effort in the cancer field has been worked out, including the campaign plans of the Women's Field Army of the American Society for the Control of Cancer.

It is proposed that, in place of the enlistment drive which was attempted unsuccessfully by the American Society for the Control of Cancer two years ago, effort should be made to raise funds for the work of the American Society through social functions such as balls, teas and special moving picture shows. Seventy per cent of the money raised would be allocated by the Massachusetts Executive Committee of the American Society for the Control of Cancer for cancer education in this State, and 30 per cent would go to the American Society. It is felt that this will be a much more successful and satisfactory means of raising funds than that previously attempted.

During the year, it is planned that at least a portion of the funds raised be used for the publication of a book.

covering the salient points of cancer knowledge and cancer education for distribution to the physicians of the State.

There has been careful discussion of the state aided diagnostic cancer clinics. Some suggestions had been made that they be expanded with the aid of state funds to become treatment clinics. The committee feels that such a procedure is unwise, being a further expansion of state medicine, unwarranted expenditure of state funds, and unnecessary for the proper care of cancer patients.

SHIELDS WARREN, *Chairman*

## APPENDIX NO 11

### REPORT OF THE COMMITTEE ON POSTGRADUATE INSTRUCTION

In accordance with the vote of the Council last June the committee made arrangements to present the New England Postgraduate Assembly under the auspices of the Massachusetts Medical Society, which was given on November 15 and 16, 1938, in Sanders Theater, Harvard University. The Executive Committee appointed several committees which prepared a program and made the necessary arrangements. The Program Committee especially is to be commended for providing such a fine program and such eminent instructors, who were as follows:

Dr Francis G Blake, New Haven, Connecticut  
 Dr Louis A. Bue, Rochester, Minnesota  
 Dr William L. Estes, Jr., Bethlehem, Pennsylvania  
 Dr Robert T. Frank, New York City  
 Dr Alvah H. Gordon, Montreal, Canada  
 Dr Perrin H. Long, Baltimore, Maryland  
 Dr Louis H. Nahum, New Haven, Connecticut  
 Dr Hubley R. Owen, Philadelphia, Pennsylvania  
 Dr Harvey B. Stone, Baltimore, Maryland  
 Dr Benjamin P. Watson, New York City

The total attendance at the Assembly was 925 divided as follows:

Massachusetts	722
Maine	70
New Hampshire	48
Rhode Island	32
Vermont	23
Connecticut	15
New York	5
Canada	3
Pennsylvania	2
Minnesota	1
Utah	1
Mississippi	1
West China	1
Texas	1
Total	925

The registration fee of \$3 provided enough funds to meet expenses; there was left a credit balance of \$125 which has been turned over to the Treasurer. This Council at its October meeting voted \$500 for the assembly; the money was not used.

The committee has received many favorable comments about the assembly from various individuals and hospital groups as well as from the state societies of New Hampshire and Vermont. There has been a universal expression of opinion that the assembly was a success and that it should be repeated. The medical societies of Vermont and

New Hampshire have both expressed interest in future assemblies and will probably join this society in sponsoring any future program.

The postgraduate extension courses have been carried on for the second year in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau. The courses have been given this fall in the following places:

DISTRICT	PLACE
Bristol South	New Bedford
Essex North	Lawrence
Essex South	Salem
Hampshire	Northampton
Norfolk South	Quincy
Plymouth	Brockton
Worcester	Milford
Worcester North	Fitchburg

The first session began on October 21 and the last one was held January 20. The remainder of the course will be given during the late winter and early spring. The final report of this work will be given at the next meeting of the Council. The committee wishes to report that the state and federal agencies have given valuable help. The instruction has held to the same high standards, and has improved, according to the reports of the district chairmen. The committee wishes to express particularly the thanks of the Society for the active co-operation of the United States Public Health Service and the State Department of Health in providing a teaching collection of slides and a projection lantern, which have proved very helpful in presenting the courses in syphilis and gonorrhea.

The committee wishes to report further that clinical teaching in gonorrhea and syphilis has been established on a permanent basis in Boston and Springfield. This work has been made possible by the active co-operation of the Massachusetts Department of Public Health and the United States Public Health Service with the Society. This progressive step has been taken to meet the demands of practitioners for practical instruction in the diagnosis and treatment of these diseases. These teaching clinics were opened on December 1, 1938, and will continue twice a week for twenty-five consecutive weeks.

During the past two years the committee has taken an active interest in national postgraduate affairs. This was brought to the attention of the committee especially in view of national legislation having to do with postgraduate education in all the states. Two years ago the Executive Committee considered the problem of securing the co-operation of other state societies in an effort to improve our postgraduate extension courses and any other postgraduate activities that might have wide appeal. The Executive Committee wrote each state society in regard to this idea, this resulted in the first meeting of delegates from the postgraduate committees of the various state societies during the American Medical Association meeting in 1937 at Atlantic City.

At this meeting a tentative organization was formed called the Associated State Committees on Postgraduate Medical Education, with Dr James D. Bruce, of Ann Arbor, Michigan, chairman, and the secretary of the Massachusetts committee as secretary. The second meeting of these committees was held in San Francisco in June, 1938, during the meeting of the American Medical Association. Representatives attended from Florida, Illinois, Indiana, Iowa, Kansas, Maine, Massachusetts, Michigan, New Hampshire, New Jersey, New York, Oklahoma, Oregon, South Carolina, Tennessee, Utah and Washing-

as to the propriety of such a pioneer venture. After a combined meeting of representatives of the Department of Public Health, the president of the Massachusetts Medical Society, representatives of the standing committees of the Massachusetts Medical Society on public relations, legislation, ethics and discipline, and public health, and representatives of the Massachusetts Dental Society, it was unanimously voted to approve in principle such an undertaking. The Department of Public Health and the Committee on Public Health of the Massachusetts Medical Society were asked to explore the matter further along the lines suggested and approved at this combined meeting. This exploration revealed the fact that the final authority of the paper whose representative had proposed the plan was unable or unwilling to publish the articles proposed in a manner which seemed to the Department of Public Health and to the Committee on Public Health of the Massachusetts Medical Society to be consistent with medical ethics. Before this became apparent it had been ascertained that the deans of the three important medical schools, the directors of the large hospitals and the full time teachers of medicine and surgery were in sympathy with the plan and were willing to prepare articles for such public consumption. The editors of the *Boston Evening Transcript* were then interviewed, and readily agreed to publish a series of some sixty such articles in consecutive issues of their paper and to safeguard fully the ethics of the profession.

The members of the Council have doubtless read the editorial in the *New England Journal of Medicine* of December 16, 1938. The articles which have been appearing daily in the *Transcript* under the title of "A Doctor a Day" since December 19 have been roughly grouped into four series. The first series deals with training of a physician from his premedical education until he becomes a general practitioner, a specialist or a public health officer. In the second series the public is told of what goes on in modern hospitals and of their many and varied services to medicine and nursing. In the third series the Department of Public Health describes its multitudinous activities in safeguarding the health of the citizens and in making it easy for the physicians of the State to obtain the complicated biochemical products which have become necessary for adequate practice. The fourth series not yet published will discuss certain diseases for which specific or partially specific methods of treatment have been discovered.

This is, so far as we know, the first time that physicians in any organized manner have tried in their own words and at first hand to tell the public what they think the public wants to know and ought to know about the practical aspects of medicine.

The State Department of Public Health and the Committee on Public Health of the Massachusetts Medical Society will welcome the constructive criticism of the Council of this undertaking. WILLIAM H. ROBESY, *Chairman*

## APPENDIX NO 10

### REPORT OF THE COMMITTEE ON CANCER

Through the recognition of the special interest of the Massachusetts Medical Society and the Massachusetts Department of Public Health in cancer education, a suitable program for co-operative effort in the cancer field has been worked out, including the campaign plans of the Women's Field Army of the American Society for the Control of Cancer.

It is proposed that, in place of the enlistment drive which was attempted unsuccessfully by the American Society for the Control of Cancer two years ago, effort should be made to raise funds for the work of the American Society through social functions such as balls, teas and special moving picture shows. Seventy per cent of the money raised would be allocated by the Massachusetts Executive Committee of the American Society for the Control of Cancer for cancer education in this State, and 30 per cent would go to the American Society. It is felt that this will be a much more successful and satisfactory means of raising funds than that previously attempted.

During the year, it is planned that at least a portion of the funds raised be used for the publication of a book

to charge for their services when rendered to ward patients.

It became apparent then that unless some change was made either in the language of the member hospitals' contract, or in the staff rules of our hospitals, physicians' services would in fact, be included in the benefits which the individual policyholder received under his ward contract.

We reverted to the basis upon which the idea of ward service was originally established, and has continued to function for many years. We found that this ward service had been established on the basis that there were in our community certain people who could pay no hospital charges at all or who could pay charges which were considerably below actual hospital costs. Our hospitals, being organized under the law which classified them as charitable institutions, wished and felt obligated to care for such people, even to the extent of gambling on the actual payment itself of these below-cost charges.

In consequence of this, certain doctors agreed to care for these cases without monetary compensation. These doctors were designated as staff doctors of the institution in which they served. Their reward came entirely from a sense of having been helpful to the poor, and from the experience which came with the care of large numbers of people.

And so it appeared to us that when we and our forbears had agreed to care for ward patients without pay, we did so under certain very definite and well understood circumstances.

We believed that when our hospitals became signatory to this new ward plan as offered by the Associated Hospital Service Corporation there would no longer prevail these old circumstances under which we had been giving our services free to ward patients—at least as they related to ward patients covered under this new insurance contract. We noted that the prices paid to hospitals for the care of these ward patients under the new contract were very considerably greater than the ward rates at present in force, that actual costs if not entirely met were nearly so, and that the gamble as to the payment of these costs had been entirely eliminated.

We felt, therefore, the circumstances having been changed, that we could not care for ward patients under this contract unless we were entirely free to decide in each specific case, and for ourselves, whether or not a bill for services should be rendered to them.

We, at first, approached the Associated Hospital Service Corporation in seeking to solve the difficulties which had arisen. We suggested to it that wherever the word 'ward' appeared in the member hospital contract, the word 'private' be made to precede it. This suggestion was not accepted. We next suggested that a sentence which appears in the hospital members' contract, and which reads as follows, 'The payment of physician's services shall be according to the staff rules of the hospital' be deleted and that the following language be substituted:

'Ward patients under this contract shall be understood to have the same status as that of private patients and subject to the same responsibility for payment for doctors' services. This suggestion likewise was not acceptable.

We next approached the administrative heads of our three general hospitals. It was at this point our difficulties were solved. These hospitals have now changed their staff rules. Any doctor in good standing, be he a member of the regular staff or of the courtesy staff, may care for these cases. He may accept whatever payment he and the patient agree upon as being fair. He is subject only to the hospitals' right, which they have always exercised, to determine the individual doctor's capacity to handle specific situations.

This statement must in no wise be construed as a criticism of the Associated Hospital Service Corporation. This corporation evidently had its own valid reasons for not meeting our requests. We still continue to give it our active support. We believe, however, that this experience emphasizes again the importance of being continually alert.

## APPENDIX NO 14

### REPORT FROM THE NEW ENGLAND ROENTGEN RAY SOCIETY TO THE COMMITTEE ON PUBLIC RELATIONS AND THE COUNCIL OF THE MASSACHUSETTS MEDICAL SOCIETY

A hospital insurance contract which proposes to sell the services of certain specialists in the practice of medicine along with bed and board of the patient has been printed, circulated, accepted by some hospital superintendents and offered to the public through the press without the approval of the Council of the Massachusetts Medical Society and the physicians most intimately concerned.

It is not clear that the approval of the Committee on Public Relations alone makes such a contract valid unless the same is submitted to and approved by the Council.

It is not our purpose to characterize the precipitateness with which this new contract has been launched as one of poor taste or bad faith because of inadequate consultation with those most interested, but we do desire to protest vigorously inclusion of roentgenology as a partial benefit in a hospital insurance scheme originally fostered and approved because no provision was made to sell physician's services.

It is an accepted fact established legally that the practice of roentgenology is the practice of medicine. If one specialty is included in this plan to make it more attractive and readily salable, then it is not a far cry to the inclusion of other specialties, twenty five dollars for a fracture, a maternity case, a tonsillectomy, an appendectomy or a pneumonia case.

You may say this will be guarded against by adopting the newly proposed insurance plan to pay for the physicians or surgeons services by cash benefits. Why then exclude the roentgenologist? He is a physician practicing medicine! Who shall separate the sheep from the goats? Not an insurance corporation, we hope, profit or non-profit!

The New England Roentgen Ray Society is not concerned primarily with the fact that the proposal in question may curtail the income of its individual members. Doubtless it will add to the income of many.

It is concerned with the fact that including x-ray examinations may injure the growth of the science of roentgenology, decrease the quality of the service to be offered patients, discourage the attraction of competent new matriculates in the field and seriously dislocate the relation now existing happily hereabouts for the most part between roentgenologists and the hospitals.

Roentgenology is something more than a kodak as

ton, representatives from the Council on Medical Education and Hospitals and the House of Delegates of the American Medical Association also attended this meeting. A permanent organization was effected with the above officers re-elected, and Dr Thomas P Farmer, of Syracuse, chosen as vice-chairman.

The clerical and incidental expenses incurred in connection with these meetings during the past two years, amounting to \$86.25, have been temporarily paid by the Massachusetts committee, but this money will be refunded to the Society by the associated committees after their annual meeting during the American Medical Association meeting in St. Louis next May. The work of this group is of interest and benefit to the whole profession, as it works in active co-operation with the Council on Medical Education and Hospitals and other bodies interested in this field. The committee considers that the Council should approve of this action of the committee, also the committee feels that the Society should send a delegate to the official meetings of the Associated State Committees on Postgraduate Medical Education.

The Council will be pleased to know that the Committee on Postgraduate Instruction was invited to give an exhibit at the American Medical Association meeting in St. Louis. The Committee on Educational Exhibits of the American Medical Association considers the Massachusetts postgraduate program of outstanding merit, however, due to the shortness of time and other factors this invitation was declined with thanks.

The committee makes the following recommendations:

1 That the committee be instructed to present a postgraduate assembly next fall, and that the other New England state medical societies be invited to co-operate in sponsoring such an assembly, if they so desire.

2 That the postgraduate extension courses and the teaching clinics be continued in co-operation with the government agencies, as has been done in the past.

3 That the chairman or secretary of the committee be instructed to attend the official meetings of the Associated State Committees on Postgraduate Medical Education.

FRANK R OBER, *Chairman*  
LEROY E PARKINS, *Secretary*

## APPENDIX NO 12

### REPORT OF THE COMMITTEE ON PUBLIC RELATIONS

The committee has held three meetings since the last Council meeting. Progress is being made in the establishment of district health councils, which were endorsed by you in June, 1936, and later urged by the trustees of the American Medical Association.

The Subcommittee on Social Legislation and Insurance is studying currently operating and proposed plans for medical indemnity insurance.

We have a special subcommittee to stimulate discussions leading to fundamental understandings between anesthetists, pathologists and roentgenologists and hospitals. This committee had not received reports from these groups in time for discussion at our last meeting. We believe that when these special groups can agree with hospitals on matters in controversy that insurance contracts will be adjusted to comply.

We call the following to your attention:

A. The committee favored the extension of prepayment hospital service by the Associated Hospital

Service Corporation so as to include private ward patients. Where local practice does not now permit this service, permissive hospital regulations may perhaps be initiated, such as were consummated in Middlesex North under Dr Tighe's stimulus. Your district public relations member has a written report of how this was accomplished.

B. The committee has considered in principle a plan contemplated by the Associated Hospital Service Corporation for insurance to cover physicians' charges coincident with simultaneous insured hospitalization. We urge your endorsement of this principle and request your authorization to work out the details with the corporation—the plan to be initiated after agreement on its provisions.

C. The Farm Security Administration has plans (approved in principle by the Bureau of Medical Economics of the American Medical Association) providing loans to farmers for payment of doctors' bills. Approximately 700 families might be eligible for this service in Massachusetts. Twenty-one such plans are operating in the United States with approval of state and county medical societies.

The committee recommends your approval of this principle and asks authority to work out details which would be acceptable in Massachusetts, the plan to be come operative after agreement on its provisions.

Two matters were referred by the Council for consideration:

(1) The recommendation by the American Medical Association that we establish in Massachusetts a Committee on Industrial Health. We recommend that the President be authorized to establish a special Committee on Industrial Health to proceed at once to study the problems in this field in Massachusetts.

(2) The suggestion of annual physical examinations for physicians under the sponsorship of the Massachusetts Medical Society is referred back to the Council without recommendation.

ELMER S BIGNALL, *Secretary*

## APPENDIX NO 13

### REPORT CONCERNING HOSPITAL RELATIONS UNDER THE NEW HOSPITAL INSURANCE CONTRACT

I am submitting, at the direction of the Committee on Public Relations of the Massachusetts Medical Society, the manner in which the staffs of Lowell's three general hospitals met the difficulties occasioned by the adoption of the Associated Hospital Service Corporation's new ward contract.

This corporation issues for each type of service sold two contracts, one to which the individual policyholder becomes a party, and the other which is signed by the member hospital furnishing the service.

In examining these two contracts of the same type, we find that the contract signed by the individual policyholder specifically said that services of attending physicians were not included in the benefits promised. In examining the contract of the member hospital we found the following language: "The payment for doctors' services shall be according to the staff rules of the member hospital."

The staff rules of our three hospitals forbade physicians

to charge for their services when rendered to ward patients.

It became apparent then that unless some change was made either in the language of the member hospitals' contract, or in the staff rules of our hospitals, physicians' services would, in fact, be included in the benefits which the individual policyholder received under his ward contract.

We reverted to the basis upon which the idea of ward service was originally established, and has continued to function for many years. We found that this ward service had been established on the basis that there were in our community certain people who could pay no hospital charges at all or who could pay charges which were considerably below actual hospital costs. Our hospitals, being organized under the law which classified them as charitable institutions, wished and felt obligated to care for such people, even to the extent of gambling on the actual payment itself of these below-cost charges.

In consequence of this, certain doctors agreed to care for these cases without monetary compensation. These doctors were designated as staff doctors of the institution in which they served. Their reward came entirely from a sense of having been helpful to the poor, and from the experience which came with the care of large numbers of people.

And so it appeared to us that when we and our forbears had agreed to care for ward patients without pay, we did so under certain very definite and well understood circumstances.

We believed that when our hospitals became signatory to this new ward plan as offered by the Associated Hospital Service Corporation there would no longer prevail these old circumstances under which we had been giving our services free to ward patients—at least as they related to ward patients covered under this new insurance contract. We noted that the prices paid to hospitals for the care of these ward patients under the new contract were very considerably greater than the ward rates at present in force, that actual costs if not entirely met were nearly so, and that the gamble as to the payment of these costs had been entirely eliminated.

We felt, therefore, the circumstances having been changed, that we could not care for ward patients under this contract unless we were entirely free to decide in each specific case, and for ourselves, whether or not a bill for services should be rendered to them.

We, at first, approached the Associated Hospital Service Corporation in seeking to solve the difficulties which had arisen. We suggested to it that wherever the word "ward" appeared in the member hospital contract, the word "private" be made to precede it. This suggestion was not accepted. We next suggested that a sentence which appears in the hospital members' contract, and which reads as follows, "The payment of physician's services shall be according to the staff rules of the hospital," be deleted and that the following language be substituted:

Ward patients under this contract shall be understood to have the same status as that of private patients and subject to the same responsibility for payment for doctors' services. This suggestion likewise was not acceptable.

We next approached the administrative heads of our three general hospitals. It was at this point our difficulties were solved. These hospitals have now changed their staff rules. Any doctor in good standing, be he a member of the regular staff or of the courtesy staff, may care for these cases. He may accept whatever payment he and the patient agree upon as being fair. He is subject only to the hospitals' right, which they have always exercised, to determine the individual doctor's capacity to handle specific situations.

This statement must in no wise be construed as a criticism of the Associated Hospital Service Corporation. This corporation evidently had its own valid reasons for not meeting our requests. We still continue to give it our active support. We believe, however, that this experience emphasizes again the importance of being continually alert.

R. S. PERKINS,  
M. A. TIGHE

#### APPENDIX NO 14

##### REPORT FROM THE NEW ENGLAND ROENTGEN RAY SOCIETY TO THE COMMITTEE ON PUBLIC RELATIONS AND THE COUNCIL OF THE MASSACHUSETTS MEDICAL SOCIETY

A hospital insurance contract which proposes to sell the services of certain specialists in the practice of medicine along with bed and board of the patient has been printed, circulated, accepted by some hospital superintendents and offered to the public through the press without the approval of the Council of the Massachusetts Medical Society and the physicians most intimately concerned.

It is not clear that the approval of the Committee on Public Relations alone makes such a contract valid unless the same is submitted to and approved by the Council.

It is not our purpose to characterize the precipitateness with which this new contract has been launched as one of poor taste or bad faith because of inadequate consultation with those most interested, but we do desire to protest vigorously inclusion of roentgenology as a partial benefit in a hospital insurance scheme originally fostered and approved because no provision was made to sell physicians' services.

It is an accepted fact established legally that the practice of roentgenology is the practice of medicine. If one specialty is included in this plan to make it more attractive and readily salable, then it is not a far cry to the inclusion of other specialties, twenty-five dollars for a fracture, a maternity case, a tonsillectomy, an appendectomy or a pneumonia case.

You may say this will be guarded against by adopting the newly proposed insurance plan to pay for the physicians or surgeons' services by cash benefits. Why then exclude the roentgenologist? He is a physician practicing medicine! Who shall separate the sheep from the goats? Not an insurance corporation, we hope, profit or non-profit!

The New England Roentgen Ray Society is not concerned primarily with the fact that the proposal in question may curtail the income of its individual members. Doubtless it will add to the income of many.

It is concerned with the fact that including x-ray examinations may injure the growth of the science of roentgenology, decrease the quality of the service to be offered patients, discourage the attraction of competent new matriculates in the field and seriously dislocate the relation now existing happily hereabouts for the most part between roentgenologists and the hospitals.

Roentgenology is something more than a Kodak as

ton representatives from the Council on Medical Education and Hospitals and the House of Delegates of the American Medical Association also attended this meeting. A permanent organization was effected with the above officers re-elected, and Dr. Thomas P. Farmer of Syracuse, chosen as vice-chairman.

The clerical and incidental expenses incurred in connection with these meetings during the past two years, amounting to \$2625, have been temporarily paid by the Massachusetts committee, but this money will be refunded to the Society by the associated committees after their annual meeting during the American Medical Association meeting in St. Louis next May. The work of this group is of interest and benefit to the whole profession as it works in active co-operation with the Council on Medical Education and Hospitals and other bodies interested in this field. The committee considers that the Council should approve of this action or the committee also the committee feels that the Society should send a delegate to the official meetings of the Associated State Committees on Postgraduate Medical Education.

The Council will be pleased to know that the Committee on Postgraduate Instruction was invited to give an exhibit at the American Medical Association meeting in St. Louis. The Committee on Educational Exhibits of the American Medical Association considers the Massachusetts postgraduate program of outstanding merit; however due to the shortness of time and other factors this invitation was declined with thanks.

The committee makes the following recommendations:

1. That the committee be instructed to present a postgraduate assembly next fall, and that the other New England state medical societies be invited to co-operate in sponsoring such an assembly, if they so desire.
2. That the postgraduate extension courses and the teaching clinics be continued in co-operation with the government agencies, as has been done in the past.
3. That the chairman or secretary of the committee be instructed to attend the official meetings of the Associated State Committees on Postgraduate Medical Education.

#### APPENDIX NO. 14

##### REPORT FROM THE NEW ENGLAND ROENTGEN RAY SOCIETY TO THE COMMITTEE ON PUBLIC RELATIONS AND THE COUNCIL OF THE MASSACHUSETTS MEDICAL SOCIETY

A hospital insurance contract which proposes to sell the services of certain specialists in the practice of medicine along with bed and board of the patient has been printed, circulated, accepted by some hospital superintendents and offered to the public through the press without the approval of the Council of the Massachusetts Medical Society and the physicians most intimately concerned.

It is not clear that the approval of the Committee on Public Relations alone makes such a contract valid unless the same is submitted to and approved by the Council.

It is not our purpose to characterize the precipitateness with which this new contract has been launched as one of poor taste or bad faith because of inadequate consultation with those most interested, but we do desire to protest vigorously inclusion of roentgenology as a partial benefit in a hospital insurance scheme originally fostered and approved because no provision was made to sell physicians services.

It is an accepted fact established legally that the practice of roentgenology is the practice of medicine. If one specialty is included in this plan to make it more attractive and readily salable, then it is not a far cry to the inclusion of other specialties, twenty five dollars for a fracture, a maternity case, a tonsillectomy, an appendectomy or a pneumonia case.

You may say this will be guarded against by adopting the newly proposed insurance plan to pay for the physicians or surgeons services by cash benefits. Why then exclude the roentgenologist? He is a physician practicing medicine! Who shall separate the sheep from the goats? Not an insurance corporation, we hope, profit or non profit!

The New England Roentgen Ray Society is not concerned primarily with the fact that the proposal in question may curtail the income of its individual members. Doubtless it will add to the income of many.

It is concerned with the fact that including x-ray examinations may injure the growth of the science of roentgenology; decrease the quality of the service to be offered patients, discourage the attraction of competent new matriculates in the field and seriously dislocate the relation now existing happily hereabouts for the most part between roentgenologists and the hospitals.

Roentgenology is something more than a kodak as

you go' process. It is an important part of the practice of medicine.

Already one supervisory insurance board dictates what kind of equipment and films the roentgenologist shall use and the number of films that may be exposed for any given condition!

In a few localities, hospital superintendents, encouraged unfortunately by the medical staff, have proposed that the roentgenologist be employed by the hospital for the sole purpose of supervising the technical production of x ray films, the interpretation to be made by any member of the visiting staff. This system is in actual operation not in an urban small community hospital but in a large metropolitan Midwest teaching hospital.

Don't assume the attitude it can't happen here! Within two weeks a contract was submitted to one of our large hospitals where technical expense and the roentgenologist were definitely divorced. To the credit of this hospital superintendent it was rejected!

Again let us reiterate that our opposition to the hospital insurance contract as now circulated is not for the purpose of perpetrating a monopoly but for that of protecting the quality and the survival of an important medical specialty.

We have no quarrel with the hospital that engages a competent radiologist or radiologists on a salary or fee basis. We recognize the right of the hospital that supplies equipment, floor space, light, heat and attendants to remuneration and depreciation. We believe that a reserve should be set up to provide new equipment and increase the remuneration of the physician specialists in charge. We do believe however that no x ray department should be operated at the expense of itself in equipment and personnel for the benefit of any other hospital service.

On behalf of the New England Roentgen Ray Society we respectfully direct your attention to the report of the Council on Medical Education and Hospitals (*J A M A* III 158, 1938) made to and accepted by the House of Delegates at the annual meeting of the American Medical Association in San Francisco concerning the relation of roentgenologists, pathologists and anesthetists to various hospital insurance plans. Several resolutions which were offered from various sections of the country were considered by the Council on Medical Education and Hospitals. The Council in its report said:

The proposers of these resolutions, the delegates from the Massachusetts Medical Society, members of the California Medical Association and others met with the Council to express their views concerning the problems that concern the practice of medicine in hospitals by radiologists, pathologists, and anesthetists. These problems have been rendered more acute by the rapid extension of systems of group hospital insurance within the last few years. The Council believes that these problems are of vital concern to the medical profession, that unwise decisions at this time may lead to consequences that would be disastrous to physicians and to the public alike, and that, therefore, a serious study should be made of existing relations between hospitals and the physicians practicing therein, especially in the departments of anesthesia, radiology and pathology, and physical therapy, with a view to standardizing the relation of these services to the hospital, and where necessary, of reaffirming the principles of ethics involved.

The Council recommends that it, jointly with the Bureau of Medical Economics, be authorized to undertake these studies and to confer with other interested agencies, in order that it may be in a position to establish ethical standards for the practice of medicine

by physicians holding positions in hospitals and to prevent the exploitation of either the public or the profession. If during this study it is revealed that hospitals registered and approved by the Council are exploiting the public or the profession such approval may be revoked.

This report of the Council on Medical Education and Hospitals was adopted by the House of Delegates of the American Medical Association. A suitable study is in progress and recommendations no doubt will be drawn up for submission to the House of Delegates at the next annual session in May, 1939.

Until new recommendations are made and until the House of Delegates has adopted them, the policy of the American Medical Association in relation to these matters remains unchanged. Should there be doubt as to its policy in this connection it is well to remember the action taken by the House of Delegates at San Francisco which reads:

Since some state and county medical societies may find it necessary to develop preferable procedures for supplying the needs where medical services are insufficient or unavailable, it is urged that these medical societies be guided in the development of these procedures by the ten principles adopted by the House of Delegates in 1934. The application of these ten principles to specific suggestions or proposals for the organization of medical services may be facilitated by utilizing the method of direct cash payments to individual members. Your committee unanimously concurs in the suggestion and recommends that the American Medical Association adopt the principle that in any place or arrangement for the provision of medical services the benefits shall be paid in cash directly to the individual member. Thus, the direct control of medical services may be avoided. Cash benefits only will not disturb or alter the relations of patients, physicians, and hospitals.

Your committee has considered in detail that portion of the report of the Board of Trustees devoted to the Bureau of Medical Economics under the heading Group Hospitalization and also the separate statement of the Bureau of Medical Economics entitled "Group Hospitalization Insurance." Your committee commends the clarity and forcefulness of these statements and recommends that the ten principles adopted in 1934 as the policy of the American Medical Association be amplified by the addition of the following statement to Principle 4:

If for any reason it is found desirable or necessary to include special medical services such as anesthesia, radiology, pathology or medical services provided by outpatient departments, these services may be included only on the condition that specified cash payments be made by the hospitalization organization directly to the subscribers for the cost of the services.

Disapproval of the inclusion of special medical services on a service basis in hospitalization insurance contracts will then be explicit but a constructive alternative arrangement will be possible.

These actions should make clear the point of view of the American Medical Association in this regard. The action taken by the House of Delegates in San Francisco holds that it is desirable to permit each person to receive the benefits from a hospital insurance system in cash so that he may purchase his own medical services from whatever source he may desire. When the individual

himself pays for the services he receives he can be assured of adequate and satisfactory services, otherwise he can refuse to make the payment. Under the cash-to-the-insured payment arrangement, which is the long-established method used by accident and health insurance companies, the insured person receives a definite number of dollars with which he can purchase services that are satisfactory to him. He does not have to accept whatever services may be offered by the insuring organization. The rights of the patient certainly are superior to those of the hospital, the corporation or any other interest.

In view of the study being made by the American Medical Association we, duly authorized to act on behalf of the New England Roentgen Ray Society, ask that the Committee on Public Relations and the Council of the Massachusetts Medical Society hold in abeyance final approval of any hospital insurance contract that attempts to sell physicians services until the combined committees of our parent national organization have reported and published their findings for our guidance.

CHARLES W BLACKETT,  
FREDERICK W O'BRIEN,  
FRANK E WHEATLEY \*

Committee elected at a regular meeting of the New England Roentgen Ray Society Friday January 20 1939

## APPENDIX NO 15

### REPORT FROM THE NEW ENGLAND SOCIETY OF ANESTHESIOLOGY

Medical service is still in the contract of the Associated Hospital Service Corporation in spite of repeated requests by the New England Society of Anesthesiology (formerly, Boston Society of Anesthetists). The Lane Resolution has not been recognized or considered by the Massachusetts Medical Society.

The new contract of the Associated Hospital Service Corporation is to go into effect today with medical service, including anesthesia, still included in its contract, after repeated requests through resolutions of the New England Society of Anesthesiology to have this medical service excluded. Dr Nathaniel Faxon stated January 12, 1939, that this was the result of a favorable report from the Committee on Public Relations to the effect that the pathologists, roentgenologists and anesthesiologists were in agreement as to their inclusion in the contract. On the same date the committee representing the anesthesiologists received a letter from Dr Frank Dunbar, chairman of a subcommittee of the Committee on Public Relations, asking for a report from the pathologists, roentgenologists and anesthesiologists as to the results of their conferences with the Hospital Council of the Massachusetts Hospital Association, which he stated was to be presented to the Committee on Public Relations for the benefit of the Associated Hospital Service Corporation in writing its new contract.

The anesthesiologists feel that the real issue in the matter is that anesthesia, being strictly a medical service should be excluded from any insurance contract. The anesthesiologists have taken this stand right from the start of the hospital prepayment insurance contract.

## APPENDIX NO 18

### RESOLUTION PRESENTED BY DR. ERNEST L. HUNT

WHEREAS, within our population there is a considerable group who cannot be classed as indigent but whose incomes do not exceed a bare existence level and for whom adequate medical care other than through charity is not provided by any existing agency, and

WHEREAS, so far this Society has taken no effective steps toward a solution of this problem, and

WHEREAS, agencies outside the ranks of organized medicine are pressing for action looking to the provision of medical service for this low income group for which reason the initiative may pass from our control and result in

ill advised plans detrimental to patient and physician alike, be it therefore

ORDERED by the Council that the Committee on Public Relations (or a special committee of five appointed by the Chair) study the problems of medical service for this low-income group particularly in relation to voluntary insur-

ance, co-operative or contract service plans, determine the principles which this society may properly endorse, and secure or devise acceptable plans for furnishing and administering such medical service. This committee shall submit its report with recommendations to the Council at a subsequent meeting

## REPORT ON MEDICAL PROGRESS

### CLINICAL PATHOLOGY (LABORATORY MEDICINE)

WILLIAM T. SALTER, M.D.\*

BOSTON

AMONG physicians at large, there exists much disagreement about the status of clinical pathology. In a recent address on this subject, Maynard<sup>1</sup> has described the clinical pathologist as 'a consulting physician whose chief interest lies in the diagnosis of disease by laboratory methods.' Such a consultant is expected to aid in the diagnosis of diseases which differ as widely as cancer, typhoid fever and pernicious anemia. Whether such diversified problems should be included under one heading is problematical. If, as Maynard contends, "the clinical pathologist is a physician, not an overpaid technician," should not the laboratory procedures involved be entrusted to competent technicians under the supervision of physicians with active clinical interests and laboratory training? As Maynard himself points out, "it has been suggested that clinical pathology is a specialty only of convenience, not of necessity."

Apart from this administrative problem, however, it is clear that the information furnished by the six senses, including common sense, is being supplemented and confirmed by laboratory medicine in an ever-increasing degree. Almost every week an improvement appears which increases the accuracy or convenience of laboratory diagnosis. Most of these improvements are of interest only to the technically minded. In recent times, however, such advances have opened up for clinicians and general practitioners new methods of diagnosing and treating their patients.

#### DRUG LEVELS IN BLOOD

One such advance has been the measurement of sulfanilamide in the blood. The method of Marshall, Emerson and Cutung<sup>2</sup> has enabled the physician to know how well the body fluids of his patient are saturated with the specific medication. It has been amply demonstrated that concentrations of 10 mg per cent or higher are often de-

sirable. In gonorrheal arthritis, for example, Coggeshall and Bauer<sup>3</sup> have preferred to maintain the blood level close to 12 mg per cent, although occasionally concentrations as high as 20 mg per cent may be tried cautiously. Ordinarily the dose used is 0.07 to 0.10 gm per pound of body weight. Even with doses as large as 7 gm daily, however, it has been possible to guard against too heroic saturation of the system with a substance which is potentially toxic. This is feasible only through laboratory control. In cases of suppressed or impaired renal function, the drug must be used in small doses and with great care because in renal failure excretion is slow, and the drug remains to accumulate in body fluids. In the care of such cases the laboratory is especially important.

The method for estimating the concentration of the drug in body fluids is a simple colorimetric procedure. It depends on the formation of a purplish-red dye. This dye is made by diazotization of the aminobenzenesulfonamide with nitrous acid, followed by coupling of this diazo compound with dimethyl- $\alpha$ -naphthylamine. The reaction is given by many aniline derivatives, and serves, therefore, to indicate both the pure drug and its degradation products in the body.

The method is applicable to less than 2 cc of blood and to 1 cc of urine. Indeed, MacLachlan, Carey and Butler<sup>4</sup> have described a procedure which requires merely 0.1 cc of capillary blood. This modified method measures both the free and acetylated dye, and can be applied to the newer pyridine derivative by the use of an appropriate arithmetical factor. In human urine much of the drug is excreted in a conjugated form, which must be hydrolyzed with hot acid before the colorimetric method is performed.

Another example of controlled therapy is the estimation of blood bromide, as described by Brodie and Friedman<sup>5</sup>. This may be useful in the control of epilepsy and allied conditions. In

\*Assistant professor of medicine, Harvard Medical School; associate physician, Collis P. Huntington Memorial and Peter Bent Brigham hospitals.

general, symptoms of bromidism tend to occur when the bromide concentration in the blood serum exceeds 20 cc of N/10 bromide per 100 cc. Likewise, the use of thiocyanate can be regulated by analysis of the patient's blood.

This principle of measuring the concentration of medication in the blood is scientifically sound and will doubtless find application in other therapeutic procedures. Such methods correct for variations in absorption, destruction and excretion of drugs, and thus admit of better therapeutic control.

#### ENZYMES IN BLOOD

Another development of recent years has been the measurement of apparent enzyme concentration or activity in the blood. In particular, this technic has been applied successfully to two enzymes in ways which aid clinical diagnosis or therapy. The first of these is the measurement of phosphatase, the enzyme which hydrolyzes organic esters of phosphoric acid. Several procedures have been described for determining the apparent concentration or activity of this enzyme in the blood. The result is expressed in "units" per given volume of blood. The older units of Kay<sup>6</sup> and Bodansky<sup>7</sup> have been superseded in many clinics by the newer unit of Jenner and Kay.<sup>8</sup>

In Paget's disease (arthritis deformans), in hyperparathyroidism, in rickets, and in tumors involving bone, repeated phosphatase determinations serve not merely to confirm the diagnosis but also to gauge the activity of the disease at successive intervals of time. Thus in Paget's disease, the phosphatase may be normal during remissions. Phosphatase is also increased in certain liver diseases, particularly those associated with jaundice.

Recently Gutman and Gutman<sup>9</sup> have described an increased "acid" phosphatase activity in the serum, found in 11 of 15 patients with metastasizing prostatic carcinoma. It differs qualitatively from the "alkaline" phosphatase of the serum, but resembles closely the phosphatase of prostatic tissue.

The second enzyme is amylase, the enzyme concerned with the splitting of animal starch (glycogen) into glucose. Here again, the result is expressed in "units" per given volume of blood. For the determination, various modified procedures are available, of which that of Cope, Hagströmer and Blatt<sup>10</sup> is representative. Minor fluctuations are found in diabetes and after insulin or x-ray therapy. Low values are found in von Gierke's disease. The method's greatest usefulness is in the diagnosis of pancreatitis, cases of which show a remarkably high value for amylase, as described by Cole.<sup>1</sup> The importance of this finding is obvious in view of the desirability of conservative treatment in acute pancreatitis. Furthermore, repeated deter-

minations of enzyme activity serve to measure the progress of the lesion, when co-ordinated with other clinical findings.

Doubtless other enzymes will be measured and subjected to practical use in the near future. In developing methods for this purpose, it is necessary to remember that the effect produced by an enzyme is often not proportional to its concentration.

#### VITAMINS IN BLOOD AND URINE

Similar methods are being employed in the diagnosis of incipient avitaminosis and in vitamin therapy. Thus far, the method has been applied successfully to vitamin C only. For some years, however, such methods have been widely used with dubious or even fallacious results. A chief difficulty is that this vitamin exists in two forms, and the physiological significance of one—the dehydrogenated form—has not been determined. Another difficulty is that the reagent commonly employed to detect reduced vitamin C, namely dichlorophenolindophenol, is affected by substances other than the vitamin. Recently, however, the methods for urine have been improved by Evelyn, Malloy and Rosen,<sup>12</sup> and for blood by Mindlin and Butler.<sup>13</sup> The average serum level is approximately 0.8 mm per cent. In frank scurvy, practically no reduced vitamin C can be detected in the serum, as shown by van Eekelen<sup>14</sup> and others. Values between 0.2 and 0.5 mm per cent are of dubious significance. This is so because the concentration of reduced vitamin in the serum falls very rapidly when the vitamin has been withheld for only a short period.

In the milder cases of dietary deficiency, in the "twilight zone of vitamin lack" described by Minot, this method will doubtless prove of value. It may prove useful, too, in rheumatic and other infections, as suggested by Faulkner and Taylor.<sup>15</sup> Under ordinary clinical conditions at the present time, probably the safest procedure to employ is the study of the vitamin-tolerance curve described by Abbasy, Harris, Ray and Marrack<sup>16</sup> and others. When ascorbic acid is fed to normal individuals, much of it is rapidly excreted in the urine. On the contrary, patients who lack the vitamin retain the administered ascorbic acid and consequently fail to excrete much of it in the urine. Thus one may detect depletion of stores of ascorbic acid in the body.

Doubtless other vitamins will be measured in the blood through years to come, but none of them can be estimated accurately enough for clinical purposes at the present time.

#### ELECTROPHOTOMETRY

The application of the photoelectric cell to clinical laboratory methods bids fair to supplant the

visual colorimeter in clinical and research laboratories. At present all available electrophotometers are susceptible to improvement, but even now their usefulness is clearly apparent. Under suitable conditions, accurate readings can be made in a few seconds in concentrations too weak for the eye to detect. Furthermore, extraneous colors can be screened out by suitable light filters or by the use of a spectrophotometric system giving monochromatic light. These instruments will soon cost little more than colorimeters of comparable accuracy and will provide for a great saving of labor and time. Furthermore, they permit the application of methods unsuited to the colorimeters now available, and facilitate estimation of one tenth to one twentieth of the colored or chromogenic substance required for ordinary colorimetry. Indeed, the electrophotometer may be equipped with a micro attachment, which permits analysis of less than a cubic centimeter of final solution. For chemical tests in children and in small animals, this extension is helpful. It can also be used as a nephelometer to determine protein in spinal fluid or fat in blood plasma. In fact, the instrument is extremely sensitive to turbidity, and this fact must be remembered in applying it to colorimetric work. For detailed descriptions of such methods, one should refer to the articles of Evelyn and Malloy<sup>17</sup> and Sanford, Sheard and Osterberg.<sup>18</sup>

Other electrophotometers are available, and each has its respective appeal to the individual technician. Each of these instruments provides as nearly monochromatic light as possible in that region of the spectrum where maximum absorption is to be expected for the specific colored substance involved. The instrument then measures the amount of light absorbed through the action of a photoelectric cell, which is connected to a suitable electrical system containing a galvanometer. The concentration of the colored substance should be proportional to the logarithm of the light absorbed, according to the fundamental laws of Lambert and Beer.

This type of instrument has been applied to hematological procedures. It measures hemoglobin concentration within 2 per cent. This can be done even when methemoglobin is present, a circumstance which renders the Sahli method impracticable. In cases treated with sulfanilamide, this is a distinct advantage.

How far this type of instrument can be applied to clinical hematology is still a matter of conjecture. Various laboratory studies are in progress which suggest interesting possibilities. After hemorrhage, for example, in otherwise normal blood, the instrument can often be used to determine

"cell opacity." From this value the hematocrit can be calculated, under certain conditions. (A convenient routine is to measure the cell opacity, then, after adding a little saponin to hydrolyze the red cells, to measure hemoglobin.<sup>19</sup>)

It has been suggested that under favorable conditions the instrument might be used to count red cells or to determine red-cell diameter. Such attempts must at present be regarded with suspicion, however, because variation in size and shape of the red cells tends to distort the result seriously. Nevertheless, for those interested in investigation, the suggestion is intriguing. It will be recalled that in the last century, Thomas Young devised an "eriometer," by which he measured the diameter of red blood cells, having calibrated his instrument with lycopodium spores. It is conceivable that the electrophotometer might be used to measure interference effects in this manner.

#### HEMATOLOGICAL PROBLEMS

The severe hemolytic crises occasionally produced by sulfanilamide present a difficult problem. Blood destruction is so profound that the bone marrow response projects many immature forms, such as megaloblasts, into the circulating blood. There is a clinical impression that transfusion at this time may be followed by untoward results, but the problem is not yet clear. Under such circumstances, of course, use of the drug should be discontinued.

The extensive use of sulfanilamide has also raised an interesting problem with regard to the severe cyanosis and anemia which it produces not infrequently. Originally these findings were supposed to be the result of methemoglobin or sulfhemoglobin formation. Recent studies by Chesley<sup>20</sup> and Hartmann, Perley and Barnett,<sup>21</sup> however, indicate that these substances are not the chief cause of the cyanosis. Indeed, in some cyanotic cases, nearly all the hemoglobin seems to be active in adding molecular oxygen. The actual mechanism of the cyanosis, therefore, remains obscure. It has been suggested that the color is due to an unusual black pigment, closely allied but not identical to methemoglobin. The spectral characteristics of the colored substance are essentially the same as those of methemoglobin; that is, both give absorption bands at 635  $\mu$ . Possibly the difference is due to the environment. At any rate, there is some evidence that the pigmentation may be reversed by administering methylene blue. Such observations remind one of the peculiar dark pigment described by Loeb, Bock and Fitz<sup>22</sup> in cases of nitrobenzene poisoning. Obviously, the problem has not as yet been solved, but it may be suspected that the ordinary methemoglobin of the biochem-

ical laboratory is not the chief reason in all cases for the characteristic cyanosis produced by the drug

In view of these hazards, which are described in a recent monograph by Mellon, Gross and Cooper,<sup>23</sup> it is clear that the drug should not be employed without close control. This implies hospitalization, or very close proximity to a hospital, and a progressive clinical laboratory. Whenever the drug is used, it is desirable to determine the red-cell count, the leukocyte count and the drug level in the blood every two or three days.

Transfusion technic is again under scrutiny. There are no new major difficulties involved, but rather the question of effectively guarding against well-known complications. This journal has recently published a letter<sup>24</sup> regarding the danger of incompatibility in transfusion.

The transfer of syphilis by transfusion, although an extremely uncommon accident, is receiving legislative attention. This complication usually occurs because blood is needed in an emergency and there is not time for the routine Wassermann or Hinton test, which may be reported positive several days later. In such exigencies the rapid flocculation method of Hinton,<sup>25</sup> or the micro modification of Davies,<sup>26</sup> may prove extremely useful. Hinton claims a high degree of accuracy for this simple method, which can be performed in a short time by one familiar with the technic. In this connection due regard must be paid to the so-called "zone phenomenon" when the Wassermann reaction is strongly positive, the Hinton reaction may be negative unless the serum is diluted. The micromethod has the further advantage, notable in children, that capillary blood is adequate in amount, and venipuncture therefore superfluous.

Attention should be directed again to the desirability of bone-marrow biopsy in the study of obscure anemias. To give best results, these must be properly performed and suitably handled by those familiar with the problem. One feature is the study of fresh impressions, which may be made upon slides or cover glasses by successive imprints from the excised tissue. These are fixed and stained like blood smears. The later imprints are progressively thinner, and allow one to choose appropriate fields for study. In view of time required for decalcification of the main specimen, these impressions are convenient and often highly illuminating.

#### MISCELLANEOUS PROCEDURES

In recent years a number of modifications have been introduced into standard diagnostic proce-

dures which have proved so valuable that it seems worth while to call attention to them again.

In routine blood-cell counting, the use of automatic pipettes is gaining ground. These ingenious devices are scorned by the trained technician and busy hematologist. For those practitioners who take only an occasional sample with their own hands, however, they are convenient. These pipettes have an inset capillary tube, the bore of which ends abruptly so that over-filling is avoided.

Gastric analysis has been reduced largely to a study of acidity. Many clinics use alcohol for the test meal because it is more convenient to remove and titrate than the usual test meal. In the event that no free acid is obtained in the initial sample, it is often desirable to stimulate the secretion of gastric juice by administering 0.5 to 10 mg. of histamine subcutaneously. This material, in such doses, often produces a ready flow of gastric juice, which otherwise fails for nervous or other reasons. In cases of allergy the histamine should be used cautiously, because such patients may be hypersensitive to the drug and may react with acute asthma or other unpleasant symptoms.

In determining renal function, the application of Chapman's<sup>27</sup> fractional technic for measuring excretion of phenolsulfonephthalein has aroused widespread approval. This method emphasizes the appearance of the dye within the first fifteen or thirty minutes. Thus, of two cases yielding 40 per cent of the dye within an hour, the normal would show 10 + 20 + 5 + 5 per cent in four successive fifteen-minute intervals, whereas the pathologic case would show 10 + 10 + 10 + 10 per cent. The early rise in the excretion curve is evidence of normal function, its absence indicates limitation of function, even though the total excretion be normal. The method is best adapted to intravenous administration of the dye, but can be used satisfactorily in most cases after intramuscular administration. In the latter case, the time interval is altered to allow an extra ten minutes for absorption of the dye.

In nephritis the urea clearance as developed by Moller, McIntosh and Van Slyke<sup>28</sup> may be advantageous. No injection is required. Capillary blood is adequate. In cases with residual urine in the bladder, the method is more reliable than is the phthalein test. The application of this test clinically to urea excretion at low urine volumes has been recently discussed by Chesley.<sup>29</sup>

The old familiar urinary concentration test, of course, remains valuable, and various shortened procedures have been suggested to replace the elaborate methods like those of Schlaver. A convenient modification is described by Hunter<sup>30</sup> in

the new edition of the *Laboratory Manual of the Massachusetts General Hospital*. The procedure has been reduced to three specimens overnight, 7 to 8 a m in bed, and 8 to 9 a m ambulatory. These specimens are examined for specific gravity and albumin. Orthostatic albuminuria should be detected by the examination of the last specimen.

The Takata-Ara test for high globulin in body fluids seems doomed to abandonment in favor of the formol-gel test. This simple gel formation of a formalin-protein complex is useful as a qualitative test. It was first observed by Gaté and Papacostas<sup>31</sup> and has been applied in various modifications. Bing<sup>32</sup> has discussed the results obtained in Denmark by the following method. Two drops of 40 per cent formalin solution are added to 1 cc of serum in a small test tube. Three hours later the tube is inverted to test for complete gelification. Plasma must not be used, because the normal (globulin) fibrinogen reacts with the reagent. Hyperglobulinemia occurs in cases with multiple myelomas, kala-azar, liver disease, certain infections and, occasionally, lymphoma and lymphatic leukemia.

Another test of plasma protein is the falling-drop method, which in fact measures specific gravity. Moore and Van Slyke<sup>33</sup> showed a striking proportionality between the specific gravity of the serum and its protein content. Later Barbour and Hamilton<sup>34</sup> developed a falling drop method for determining specific gravity, and Kagan<sup>35</sup> has combined the two to determine the total protein content of plasma or serum. The principle is an application of Stokes' law, which states that the rate of fall of a small solid sphere in a viscous liquid depends on the radius and specific gravity of the sphere, the specific gravity and viscosity of the fluid, and the acceleration due to gravity. Under appropriately controlled conditions, the protein content of the drop may be determined from its rate of fall in a suitable oil. The amount of serum or plasma required is less than 0.05 cc.

This method is proving very satisfactory in the treatment of dehydration, whether by physicians or by surgeons. In addition to frequent determinations of serum protein, estimations of plasma sodium and chloride are desirable. Further details will be found in this *Journal* in a forthcoming review by Butler.<sup>36</sup>

In recent years the tryptophane reaction in the cerebrospinal fluid has attracted increasing attention. In 1927 Aiello<sup>37</sup> called attention to the presence of tryptophane in the cerebrospinal fluid of cases with tuberculous meningitis. The whole test can be performed in twenty minutes. The reagents contain hydrochloric acid, formaldehyde and

sodium nitrite. The positive test is read as a delicate violet ring, which is best observed in daylight against a white background. Falsely positive reactions are given by purulent, hemorrhagic and xanthochromic fluids. Spillane<sup>38</sup> has reported the results in 172 consecutive cases of various diseases. Of these, the test was positive in 30 of 32 cases of tuberculous meningitis. In 29 turbid fluids, the test was falsely positive. In all the remaining fluids the test was negative. Although the clinical value of this test has not yet been established, such preliminary reports justify extensive trial of it.

#### BOOKS

New books are constantly appearing on the subject of clinical pathology or laboratory medicine. Many of these are excellent reference books, and it is difficult to choose between them. Most of them have little to do, however, with procedures bordering on legal medicine and toxicology. Indeed for practitioners in small cities and rural communities there has been no up-to-date source of ready information of this sort in book form. This need is in a large measure met by Gonzales, Vance and Helpert's textbook<sup>39</sup> on legal medicine and toxicology, which is written in clear English and is well illustrated. Its section on carbon-monoxide poisoning is especially useful and interesting.

Another work of great value is Peters and Van Slyke's textbook<sup>40</sup> on clinical chemistry, which is published in two volumes. In the clinical laboratory this presentation of applied chemistry should be available for frequent reference. For a convenient handbook, the new *Laboratory Manual of the Massachusetts General Hospital*, edited by Hunter,<sup>30</sup> is very useful. This last book is in press, but will soon be available.

695 Huntington Avenue.

## CASE 25101

### PRESENTATION OF CASE

A fifty-year-old, unmarried Turkish grocer was admitted complaining of weakness and fever of four weeks' duration.

During the previous two months there had been a gradual loss of 40 or 50 pounds in weight, accompanied by malaise and diminishing strength. About five weeks prior to admission the patient had a cold, which was followed by mild persistent diarrhea. About a week later he began to experience increased weakness and fever, which continued until entry. At the time of onset of fever the patient entered an outside hospital where he remained for four weeks. His temperature fluctuated, reaching 101 to 102°F daily. His white blood-cell count was never over 14,000. The urine remained negative except for a very slight trace of albumin and a few white cells. He had no pain or tenderness. X-ray films showed a high diaphragm on the right. X-ray films of the gall bladder were negative. He had not had chills, pain, jaundice, edema, cough or dyspnea.

He was born in Turkey but moved to greater Boston at the age of twenty-one years. He had enjoyed good health until the onset of the present illness. Ten years ago a right mastoidectomy was performed. His past and family histories were otherwise noncontributory.

Physical examination showed a large, obese man, weighing 215 pounds, in no distress, but breathing heavily. The skin was moist and hot. There was a crusted papular rash on the legs below the knees, and marked intertrigo of the scrotum and groins. There were a few shotty inguinal nodes. Examination of the chest showed diminished expansion on both sides, more marked on the left. There were absent breath sounds and dullness over both bases posteriorly, but no rales. One examination stated that diaphragmatic excursion was limited on both sides, especially on the left. The heart was not enlarged, and there was a rough, short apical first sound with a suggestive brief systolic murmur. The blood pressure was 165 systolic, 80 diastolic. The abdomen showed bulging flanks and a probable fluid wave. There were no masses, no tenderness. Percussion showed generalized tympany. In the right scrotum there was

a transilluminable, soft, fluctuant mass measuring 4 by 5 by 6 cm.

The temperature was 101°F, the pulse 125, and the respirations 45.

A urine examination showed a specific gravity of 1.020 with a large trace of albumin and a rare white cell.

The blood showed a red-cell count of 4,400,000 with 80 per cent hemoglobin. The white-cell counts ranged from 8900 to 21,250, with 74 to 84 per cent polymorphonuclears. A blood Hinton test was positive, Wassermann negative. Two stool examinations were negative. An echinococcus skin test was negative. Typhoid, paratyphoid A and B, and undulant fever agglutination tests were negative. A blood culture showed diphtheroids in one flask and a contaminant gram-positive bacillus in the other. An electrocardiogram showed a rate of 140, regular. T<sub>1</sub> was slightly low, QRS slightly slurred. There was moderate left-axis deviation.

X-ray films of the chest showed an unusually high right diaphragm. There was hazy density above it, which obliterated the costophrenic angle. The remainder of the lung fields was clear. The heart was not displaced. X-ray films of the abdomen showed no free air beneath the diaphragm.

On the second hospital day a medical consultant stated that the patient was in a critical state and on the edge of delirium. The heart beat was rapid, regular and of ticktack quality. There was congestion of both lung bases. The abdomen was distended, peristalsis was active, but there were no signs of fluid. Liver dullness was absent, and the spleen was not palpable. During the following two days the patient had slight diarrhea. A warm stool examination showed numerous pus cells and red cells but no amebae. Cultures of this stool showed no pathogenic organisms. The spiking temperature continued. On the sixth hospital day the patient was transferred from the private wards to the general surgical service.

Physical examination was essentially unchanged. A medical consultant then suggested a malignant form of ulcerative colitis as a likely diagnosis. A surgical consultant believed that undulant fever was most likely. On the twelfth hospital day an emetin hydrochloride therapeutic test was begun. On the tenth hospital day x-ray films showed the diaphragm still high in position. Fluoroscopic examination showed fixation of the right diaphragm. There were linear areas of increased density in the right lower lung field, which appeared to represent areas of atelectasis. There was no definite evidence of fluid. An intravenous pyelogram was negative. There were no unusual abdominal soft tissue masses. A barium enema examination was nega-

tive On the tenth and eleventh hospital days blood cultures showed nonhemolytic streptococci in all flasks On the fifteenth hospital day another blood culture showed nonhemolytic streptococci in one flask At this time a gastrointestinal x-ray series showed the stomach to be high in position, but otherwise normal The duodenal cap was large, smooth in outline, and emptied poorly by gravity The duodenal loop showed a 2-cm diverticulum on the lesser curvature of the loop, but it was not otherwise remarkable There was no evidence of organic disease in the stomach or small intestine On the nineteenth hospital day a surgical consultant stated that his diagnosis was portal thrombophlebitis, with liver abscess or abscesses He believed the appendix to be the etiologic focus

The patient's temperature continued spiking daily from normal to 103°F On the twentieth day a van den Bergh test was normal, indirect On the twenty-first hospital day a third surgical consultant stated that subacute bacterial endocarditis was a tenable diagnosis, adding that a single liver abscess could not be ruled out The following day another electrocardiogram showed a regular rate of 120 T<sub>3</sub> was flat There was moderate left-axis deviation The P-R interval was 0.16 seconds On the twenty-fifth day a cardiac consultant found no evidence of enlargement of the heart, and no murmurs with the patient in various positions The blood pressure was 115 systolic, 58 diastolic He stated that he could find no evidence of heart disease Two days later dullness was found at both lung bases, and frequent crackling rales, which could be attributed to the elevated diaphragm The abdomen was soft and obese and showed no evidence of fluid There was no tenderness anywhere Several additional stool cultures showed no pathogenic organisms On the twenty-ninth day x-ray films showed the diaphragm still elevated on the right, being about 5 cm higher than on the left There was no respiratory motion on the right side Linear areas of atelectasis were present in the right lower lung field, but there was no evidence of fluid in the pleural cavity The heart was slightly enlarged The aortic knob was calcified The liver shadow did not appear to be enlarged There was questionable enlargement of the spleen Three days later a needle was introduced into the liver in three different places, but no pus or foci of resistance were encountered On the thirty-seventh hospital day the patient complained of pain in the right ear Examination showed a small perforation in the tympanic membrane which allowed a small amount of granulation tissue to protrude through, as well as a small amount of sero-sanguineous discharge A culture showed beta

hemolytic streptococci and *Staphylococcus albus* On the thirty-ninth day the patient was transferred from the surgical to the medical service

Physical examination at this time showed an ill, exhausted man, breathing rapidly There was a small hemorrhagic area on the left lower eyelid and another on the right buccal mucosa An old right mastoid scar was present, and evidence of a right otitis media At the base of the heart, just to the right of the sternum, a faint but definite diastolic murmur was heard, not present over the rest of the precordium The heart action was rapid and vigorous The first sound was reduplicated at the apex The blood pressure was 155 systolic, 50 diastolic No note was recorded relative to the character of the pulse The liver was palpable but not enlarged A definite mass palpated in the left upper quadrant was thought to be spleen The skin over the right lower leg showed deposits of brownish pigment A summary of the blood counts since admission showed red-cell counts varying from 4,200,000 to 5,080,000 with 80 to 84 per cent hemoglobin The red cells were hypochromic The polymorphonuclears showed a shift to the left

On the forty-second hospital day the diastolic murmur over the aortic area was quite plainly audible X-ray films of the mastoid processes showed a large operative defect on the right The remaining cells in the antral triangle showed considerable sclerosis On the forty-fifth hospital day, examination of the right ear showed a purulent discharge pulsating through a perforation in the lower central part of the tympanic membrane The drum was thickened and red but not pushed outward The mastoid scar showed no injection, swelling or tenderness A second culture of the ear showed an abundant growth of *Staphylococcus albus* and a few colonies of beta hemolytic streptococci The patient's fluctuating temperature and rapid pulse continued Another blood Hinton test was reported unsatisfactory Another blood culture showed nonhemolytic streptococci in both flasks The van den Bergh test was normal indirect The patient gradually failed and died on the fifty-seventh hospital day

#### DIFFERENTIAL DIAGNOSIS

DR WILLIAM B BREED I am going to reverse the usual procedure here by offering one diagnosis and then endeavoring to see if it can be substantiated I believe the patient had subacute bacterial endocarditis In addition, he had otitis media which probably had no bearing on his disease in general, he had arteriosclerosis and calcification of the aorta, he had atelectasis at the right base, with a high fixed diaphragm Before I try to

put forward supporting evidence there are certain discrepancies in observation which should be pointed out. This seemed to be another "gymnastic liver" like the ones referred to by Dr Mallory. There was certainly disagreement clinically, and x-ray study did not indicate that there was anything abnormal about the size of the liver. Then comes the question of ascites—there was considerable discrepancy between clinical opinions in this respect. My instinct leads me to say that there was no ascites, because when there is such doubt it is much safer to say that there is none. There is little said about the stool and the question of diarrhea, and although the record states that he had had some diarrhea, there was only one stool examination which showed pus and blood. The rest were negative, and there was no evidence of any pathogenic organisms or parasites.

Going back to the beginning, What are the facts that are perfectly consistent with a fundamental diagnosis of subacute bacterial endocarditis in this man? Weakness, fever and loss of weight following an upper respiratory infection are all right. The development during his three months' history of a diastolic murmur in the heart, the petechiae, the enlarged spleen and the positive blood cultures are all right, and I do not believe that we need more to establish that diagnosis. There are certain other facts that do not quite fit in with the diagnosis of endocarditis, the symptom of diarrhea being one of them. The more I read this history over the less impressed I was with that complaint, and inasmuch as only one stool showed pus and blood, I am inclined to put little emphasis on it. There was no anemia. That is another observation which one would like to have different. Progressive anemia would tend to substantiate the endocarditis more than a continuing good blood count. However, someone did note that the red cells were hypochromic.

DR TRACY B MALLORY. On the question of the number of stools, the chart indicates only one day with as many as three, and on the vast majority of days there was only one.

DR BREED. That is comforting.

Then we come to this high fixed right diaphragm. One can think of a number of things—*intrinsic* liver disease, amebic abscess, cancer, bronchiectasis and subdiaphragmatic abscess, and paralysis or injury to the right phrenic nerve—which might cause atelectasis. It seems unlikely that there would be a high fixation of the diaphragm due to atelectasis without change in the position of the mediastinum. Apparently the heart was not moved over. To say that he had no *intrinsic* disease of the liver or any serious disease below the diaphragm would be a guess.

My impression is that older people who develop subacute bacterial endocarditis usually have a more rapid course than do younger people. This was a fifty-year-old man whose disease lasted in all only three months. It is, to be sure, a rather rapid course for subacute bacterial endocarditis, in my experience, however, it is not unusual in the older group.

I should like to discuss these x-ray films more thoroughly with Dr Hampton and I should like particularly to have him explain to me, if he can, why the right diaphragm is high and fixed. That bothers me a good deal.

DR AUBREY O HAMPTON. It bothers me too. This is the examination done outside the hospital. The diaphragm was high at that time, and in this film taken two months later it is in the same position and still distinctly visible. I think that should mean that he has not a subphrenic abscess because by that time he ought to have had fluid in his chest.

DR BREED. Atelectasis of this degree would not of itself hold the diaphragm up without displacing the mediastinum, would it?

DR HAMPTON. The type of atelectasis that we see here is secondary to a high position of the diaphragm. The collapse of the whole lung would displace the mediastinum, but basal atelectasis such as this does not. In the lateral view the shape of the diaphragm is not what you usually see when it is fixed by inflammatory disease. The arc of the circle is not so short as it is here. The dome is flatter or more horizontal, and I think this is definite evidence that he did not have disease in the abdomen that caused elevation of the diaphragm. The liver shadow appears to have gone up with the elevated diaphragm in some of the films, and in others, if that is liver shadow, it is in normal position. I do not see why the gas in the bowel is higher than usual in this film, and in normal position in this one. I do not believe the diaphragm moves one day and does not the next. His left kidney is lower than the right, and I wonder if the liver and right kidney are not congenitally high, along with the diaphragm, for some cause which we do not know. I do not know whether paralysis of the diaphragm due to *eventration* or to some injury of the phrenic nerve would result in this picture. The diaphragm does not move paradoxically. The left kidney may be lower than normal. I have no real explanation for this except that in one film we get a shadow which looks like the spleen in a low position. At one time he had a lot of gas in the small bowel, the next time none. I cannot place any lesion in his bowel or in the region of the cecum, although the cecum was contracted and on examination it

seems as though it was irritated by spasm or inflammatory disease, yet we see the small bowel which was perfectly normal and we have no evidence, later, of a spastic cecum

DR BREED Your phrase "congenitally high diaphragm" I have never heard before, but it sounds well I should like to leave it as a congenitally high diaphragm on the right!

The electrocardiogram does not really help very much It certainly does not indicate coronary disease. The changes I think could perfectly well be due to his illness I think I shall still rest on one diagnosis, namely subacute bacterial endocarditis, with the various other unconnected conditions, such as otitis media, arteriosclerosis with calcification of the aorta, and high right diaphragm (congenital!) to be mentioned

DR EDWARD D CHURCHILL In reviewing the history as a whole, I think it is difficult to realize how closely this man came to being operated on We were faced with the situation of a spiking fever, an elevated white count, only one of many blood flasks showing a nonhemolytic streptococcus, a high fixed diaphragm and the assurance of the medical consultants and the cardiac consultants that the heart was normal, as it was by examination at that time We did come to the point of putting in a needle to keep from overlooking subphrenic abscess Then while he was still a puzzle to us we transferred him to the medical service, although even at that time we were not sure whether he had concealed infection in his abdomen

DR ARLIE V BOCK I commend the men on the surgical service for the way they handled this case They did not go ahead with abdominal exploration, in spite of the fact that most of the time it looked as if the patient had sepsis in the abdomen He had a high fixed diaphragm, suggesting a subphrenic abscess The abdomen seemed normal except for the presence of a palpable spleen The thing against subphrenic abscess is the fact that no pleural fluid had accumulated, and I have yet to see such a case in association with active septicemia I saw him the day he was transferred to the medical service, and no heart murmurs were present before transfer The diagnosis became very easy after the appearance of the diastolic murmur It is interesting that he had only one or two small peripheral emboli There is a point Dr Breed did not mention the patient had subacute bacterial endocarditis with no evidence of any previous heart damage This, I think, is quite a rare finding

DR BREED We are finding more of these recently, especially in the older groups

DR EDWARD F BLAND Have you encountered any other lesion with repeatedly positive cultures that did not prove to be subacute bacterial endocarditis?

DR TRACY B MALLORY No, I have not

#### CLINICAL DIAGNOSES

Subacute bacterial endocarditis

Abscess of liver

#### DR. BREED'S DIAGNOSES

Subacute bacterial endocarditis

Aortic regurgitation

Septicemia (*Streptococcus viridans*)

Otitis media

Calcification of aorta

Congenital fixation of right diaphragm

#### ANATOMICAL DIAGNOSES

Subacute bacterial endocarditis involving aortic, mitral and tricuspid valves

Cardiac cirrhosis of the liver

Cerebral embolus with small infarct of occipital cortex

Arteriosclerosis, aortic and coronary

Splenomegaly

#### PATHOLOGICAL DISCUSSION

DR MALLORY This cardiac murmur rather miraculously developed in transit from the surgical to the medical wards It is not a question of difference between medical and surgical stethoscopes because none of the medical men heard the murmur on the surgical ward, but immediately after transfer they all heard it. From that moment the diagnosis was fairly obvious It remains from my point of view, however, a very puzzling case in a couple of ways His heart was moderately enlarged, weighing 460 gm, and he did have a bacterial endocarditis—a very extensive one with involvement of the aortic and mitral valves and very large vegetations on the tricuspid valve The lungs were free from infarcts There was merely slight focal atelectasis at both bases We found no reason for the "congenitally" raised diaphragm The spleen was quite large The surprising features of the autopsy were the liver and heart When we examine the heart closely in cases of subacute bacterial endocarditis we can almost invariably find evidence of previous damage, most commonly rheumatic heart disease but of course occasionally a congenital abnormality such as a bicuspid aortic valve In this patient there was nothing to suggest any previous lesion On the other hand the liver was cirrhotic and this cirrhosis was of a peculiar character Micro-

scopically it is a classical picture of so-called cardiac cirrhosis, the fibrosis being limited to the centers of the lobules. There was no periportal cirrhosis whatever. How a cirrhosis of that sort could develop except on the basis of repeated attacks of cardiac failure, I have no idea, and yet we have nothing in the heart to suggest previous heart disease and nothing in the clinical history either, for that matter. So we have a discrepancy in anatomic evidence which I am unable to explain.

DR BREED Did syphilis play a part?

DR MALLORY He had no anatomic evidence of syphilis.

## CASE 25102

### PRESENTATION OF CASE

*First Admission* A thirty-one-year-old Finnish housewife was admitted complaining of profuse vaginal bleeding of six days' duration.

For the past year she had had intermenstrual low back pain and sharp pains in both right and left lower quadrants. Eight days before entry her regular catamenia began but continued until entry, with the passage of large clots. She was born in Finland, lived there seventeen years, then moved to Massachusetts. Physical examination was negative except for slight tenderness in the lower abdomen, tenderness over the entire perineum, retroversion of the fundus and profuse bleeding through the cervical os.

The blood showed a red-cell count of 3,100,000 with 65 per cent hemoglobin, and a white-cell count of 6800. A blood Hinton test was negative.

On the sixth hospital day a supravaginal hysterectomy was done which showed a 2-cm intramural leiomyoma.

She was discharged improved on the twentieth hospital day.

*Second Admission* (two weeks later) She had improved until three days before admission. After eating a rather large breakfast she noticed gas and epigastric discomfort. A sharp, agonizing pain in the epigastrium soon followed which seemed to be most severe over the right costal margin about 5 cm from the midline. It continued and radiated around to her back. She was tender over the right side. With the onset of the pain she vomited once, and ate nothing during the day. She was given two hypodermic injections but slept little because of the pain. On the third morning after onset she vomited some greenish material and felt partially relieved. She had two loose stools which were dark, but not tarry. A reinvestigation of her past history revealed that for the past ten years she had had attacks of moderate pain and tenderness in

the right lower quadrant lasting from half an hour to an hour and recurring at irregular, infrequent intervals. The pain was noted more often after eating fatty foods. She had been told at times by friends that her skin had a yellow tinge and had noted herself a similar color to the sclerae. Her stools had been normal and she had not vomited. Five or six years before admission a doctor had stated that she had a stone in the gall bladder.

Physical examination showed a well-developed and nourished, slightly jaundiced woman in obvious distress from severe pain. Examination of the chest was negative. The blood pressure was 125 systolic, 80 diastolic. There were tenderness and spasm in the right upper quadrant extending down to the level of the umbilicus. The gall bladder was not palpable. The remainder of the examination was essentially negative.

The temperature was 99.2°F, the pulse 85, and the respirations 23.

Examination of the urine was negative. The blood showed a red-cell count of 3,300,000 with 55 per cent hemoglobin, and a white-cell count of 6100 with 62 per cent polymorphonuclears. A blood Hinton test and spinal-fluid Wassermann test were negative.

X-ray films of the abdomen showed a stone in the region of the gall bladder or right kidney pelvis. A Graham test showed a large gall bladder filled with dense dye and a superimposed gas-filled duodenum. There were several small areas of decreased density near the fundus suggestive of gall stones. Repeat films of the right kidney showed an area of calcification in one of the middle calices, but it did not show in the lateral view. There was also moderate hydronephrosis on the right.

On the seventeenth hospital day a cholecystectomy with drainage was done. There was apparently an inflammatory cystic area in the septums between the right and left lobes of the liver. On the surface of this lay a thick-walled gall bladder, two thirds of its extent being unattached. The gall bladder was removed and showed no evidence of continuity with the cyst. It contained one 1-cm yellow brown stone. The common duct was normal. Medial to the gall bladder and continuous with the cystic area were several compressible diverticula. Inside these were multiple, impacted, rounded cystic stones measuring up to 3 mm in diameter, some containing fluid, some solid. The cyst contained 30 cc of watery, bile-stained fluid, which was not viscous. No small ducts could be found coming from the liver bed. Her jaundice cleared after operation, and she was discharged improved on the thirty-first hospital day.

*Final Admission* (nine months later) After operation she had moderate urinary frequency and constant dull pain in the right inguinal region but had no other complaints until eight days before entry when she experienced the onset of severe right upper-quadrant pain, which radiated in girdle fashion to the back beneath the scapulae and was accompanied by nausea and vomiting. The following morning her skin was yellow and she had generalized pruritus. Her stools were white, the urine dark. She had sensations of chilliness and fever. Vomiting and right upper-quadrant pain continued until two days before entry, when all her symptoms began to abate. At this time severe, intermittent pains developed across her lower back similar to those she had had before hysterectomy. Her right upper-quadrant pain, vomiting, light stools and chills were relieved. Her stools became black, which she attributed to eating blackberries.

Physical examination showed a slightly icteric, dehydrated woman in no pain. Examination of the chest was negative. The liver edge was palpated just beneath the costal margin, and 2 cm lateral to the operative incision there was a 2-cm round mass on the liver edge. Pelvic examination was noncontributory.

The temperature was 98°F, the pulse 80, and the respirations 20.

Examination of the urine showed bile, but was otherwise negative. The blood showed a red-cell count of 4,500,000 with 70 per cent hemoglobin, and a white-cell count of 9900 with 70 per cent polymorphonuclears. The serum nonprotein nitrogen was 27 mg per cent, the van den Bergh, diphasic, 712 mg per cent bilirubin, the chlorides 103 milliequivalents, the carbon-dioxide combining power 49.8 vol per cent, and the protein 7 gm per cent. An echinococcus skin test was negative. A gastrointestinal x-ray series was negative.

On the sixth hospital day her jaundice was decreasing. She had dull pain in the right upper quadrant. On the twelfth day duodenal drainage showed clear colorless fluid in which no bilirubin or cholesterol crystals were seen. Mucus and white cells were present in abundance. Two days later the blood bilirubin was 8.70 mg per cent. On the eighteenth day a laparotomy showed the liver to be of normal size and consistence. The spleen was not enlarged. The stomach was normal. The duodenum was bound to the liver by very dense adhesions. The pancreas was diffusely enlarged in its right half and was nodular. There was an irregular firm mass in the liver substance near the fissure. A contracted common duct was found, it had a diameter of 5 mm and con-

tained no bile. Sounds could be passed into the duodenum, but on passing them upward an obstruction was encountered at about the level of the bifurcation into the hepatic ducts. At this point there was a stenosis, following the dilatation of which with sounds there was a gush of bile. Just above the head of the pancreas there was a nodule which seemed to be an enlarged lymph node. A biopsy of this showed chronic inflammation.

On the second postoperative day the patient's temperature was 103°F, it returned to normal two days later. On the twenty-fifth hospital day the blood showed 17.40 mg per cent bilirubin. She had passed a brown stool, however, and seemed improved. Two days later she was severely jaundiced, the blood showing 31.3 mg per cent bilirubin and a direct van den Bergh reaction. The temperature was normal, but on the thirtieth day rose to 102°F. Three days later the prothrombin level in the blood was 45.9 per cent. Transfusions were given. On the thirty-fifth day she was bleeding from the wound and by rectum. The prothrombin level was 38.9 per cent. Vitamin K was given, and three days later the bleeding had stopped. The prothrombin level was then 64.3 per cent. On the fortieth day she developed signs of pneumonia at the right base. The sputum showed a very rare Type 3 pneumococcus. On the forty-eighth day the mouth showed ulcerations limited to the soft palate. She gradually failed and died on the forty-eighth hospital day.

#### DIFFERENTIAL DIAGNOSIS

DR LELAND S. MCKITTRICK The first admission means nothing to me so far as the subsequent story is concerned. One might wonder why a 2-cm intramural leiomyoma made her bleed, but nevertheless she had a subtotal hysterectomy with uneventful convalescence, went home two weeks after operation, and nothing further that seems in any way related appears in the course of the history.

The second admission brings us down through the x-ray examination and does not stimulate a great deal of discussion. She has a history which I should feel was perfectly consistent with gallstone attacks or attacks of biliary colic. Her friends thought she had been yellow. On physical examination she was called slightly jaundiced although we do not have that confirmed by a blood bilirubin determination. From that story and from the situation up to the present time I must confess that if I were the surgeon who saw her I should be willing to accept her as having attacks of biliary colic. The x-ray would seem to suggest that she had gallstones, and I should be will-

ing to dismiss everything by saying that she had biliary colic and that operation was indicated

"Medial to the gall bladder and continuous with the cystic area were several compressible diverticula. Inside these were multiple, impacted, rounded cystic stones measuring up to 3 mm in diameter, some containing fluid, some solid." I suspect without going into too much discussion that the operator had a little difficulty in describing what he saw. If he did not, he has certainly had difficulty describing the lesion so that I can completely visualize it.

DR. TRACY B. MALLORY: Dr. Parsons is here. He might be willing to amplify the description, if you wish.

DR. LANGDON PARSONS: I cannot add anything. I found a thick-walled gall bladder. Behind it, lying between it and the liver, was this cystic triangular area in the interlobar fissure that contained bile-stained fluid. It did not look like true bile, however, and in the substance of the medial wall of the cyst were apparent diverticula. Each one of the diverticula had a little narrow neck and was packed solid with stones, some of which were translucent and broke in my fingers. There was one faceted stone in the gall bladder.

DR. MCKITTRICK: These were the stones that seemed to have fluid in them?

DR. PARSONS: Some contained fluid and some were solid. I did not open the common duct.

DR. MCKITTRICK: I dismissed the entire first part of this history unintentionally. I do not believe one can disregard her nationality. She was born in Finland and lived there for seventeen years. I had no intention of omitting that fact. I do not see how you can discuss this case without giving serious thought to echinococcus disease.

Let us pass to the operative findings as Dr. Parsons has discussed them. The one inconsistency that I can see, and I am sure it is an inconsistency, is that the patient was supposed to be jaundiced, and I should say that no very definite cause for jaundice was found at operation. She did have a gallstone, but she had a common duct that was essentially normal. I am inclined to believe that this 1-cm gallstone was not an important feature in relation to her real disease. It is very difficult for me to evaluate completely and to interpret exactly what Dr. Parsons found. Since this abstract arrived by mail yesterday I have been thinking a great deal about his findings. I cannot for the life of me think of any condition which is characterized by pain and by the finding of such a cystic mass, with its queer contents, except some manifestation of echinococcus disease. I do not know of any liver disease that would give

this sort of picture. You might say that it was a distended bile sinus and these were small stones. You cannot have a distended bile sinus unless you have mechanical obstruction along the biliary tract which will permit back pressure and distention. I do not believe that such a lesion is common, and it is excluded in this instance by the finding of a normal common duct and also by the absence of intense jaundice. So I find it difficult to accept this queer cystic area as being due to a dilated bile sinus, and I cannot help feeling that in some way this unusual finding at operation is associated with her early life in Finland. At the present time I feel obligated to accept the fact that this probably represents some manifestation of burned out echinococcus disease.

She was perfectly well for nine months after that. Here is where I am getting into trouble again. She had a few secondary symptoms which were of no great significance. But the important thing is that she again had a recurrence of severe right upper-quadrant pain, radiating in girdle fashion to her back beneath the scapula, accompanied by nausea and vomiting and followed by jaundice, clay-colored stools and dark urine. From that we must assume that this patient then had complete obstruction of the external biliary tract. At some point, it was also associated with chilliness and fever, so I presume we could go a step farther and say there must have been an associated cholangitis. The record then states that the light stools and chills were relieved. I am not going to pay too much attention to the finding of black stools, because the finding of bloody stools might well represent mere oozing from some point in the intestinal mucosa secondary to her jaundice. It is a little hard to believe that all these findings could have been relieved in view of the further investigations, namely the finding of no bilirubin and no cholesterol crystals in the fluid obtained by duodenal drainage. If the tube was in the duodenum, have I a right to expect that there was no true bile coming through the ampulla, Dr. Jones?

DR. CHESTER M. JONES: Yes, I think that is the best test we have, provided that we are sure the fluid is colorless.

DR. MCKITTRICK: I have always considered it to be the best way of knowing whether or not bile was coming through the ampulla, although in this case it would not be in keeping with the statement above that the stools had regained their normal color. I think, however, that we can accept this as evidence of a complete block. There is one thing that does not reappear in the record, possibly because it was not an accurate clinical observation, the 2-cm mass in the region of the

incision does not seem to be mentioned any more. The liver was perfectly normal to touch, and there is no mention of a mass on physical examination.

We get into difficulty again with the record of the final operation. We are told that the liver was of normal size and consistence, the spleen was not enlarged, the stomach was normal, and the duodenum was bound to the liver by dense adhesions. The pancreas, however, is apparently coming into the picture. It was diffusely enlarged in the right half, and nodular. There was an irregular, firm mass in the liver substance near the fissure, and below this, a contracted common duct with a diameter of 5 mm, which contained no bile. That is entirely in keeping with the laboratory and physical findings of complete obstruction of the biliary tract. It is perfectly possible to have a collapsed bile duct with a mass in relation to the junction of the common hepatic and cystic ducts which occludes the external biliary tract at that point, so this is wholly in keeping with a complete block. Sounds could be passed downward into the duodenum and a common duct 5 mm in diameter which can be opened and into which sounds can be passed certainly excludes a so-called obliterative cholangitis and suggests that the obstruction was due to a localized rather than a diffuse process. When sounds were passed up the other way they met an obstruction above which was bile under pressure. We shall disregard everything in the past, for we are now faced with a patient with complete obstruction, due, I believe, to block of the external biliary tract which was probably caused by this mass which is palpated in the hilus of the liver in relation to the common hepatic bile duct. Moreover, associated with this is a nodular mass in the head of the pancreas. One lymph node was reported to show only chronic inflammation.

It seems to me we have two problems. The first is, Can we associate what was found at the second operation with what was found at the first? I think Dr Parsons will bear me out that the findings at operation the two times were quite different. Is that correct?

DR PARSONS: Yes.

DR MCKITTRICK: In other words this queer cystic area had disappeared. There was in its place, in the region of the hilus and the common hepatic duct, a hard firm mass. A probe passed through the common duct to that region reached an obstruction beyond which was a dilated duct, so that this can be accepted as the point of obstruction. Associated with that was a nodular head of the pancreas. That brings up the ques-

tion, Is the past gone and over with and are we now dealing with a different process? Or, can there be some connection between the two? I am frank to confess I could discuss this case the rest of the day and not know more than I do now. I cannot associate the present finding with what was seen nine months before. How shall we answer this problem? I believe that the mass at the hilus was malignant. Whether it was primary or secondary to a cancer of the pancreas is more difficult to decide. It would seem to me that she must have had in the pancreas either chronic pancreatitis or carcinoma. As a rule it is impossible for an operator to distinguish between the two by palpation. I do not believe that the presence of chronic inflammation in the lymph node is of any significance one way or the other. It is impossible for me to make an accurate diagnosis, but I have to say something and it seems to me the diagnosis which fits the physical picture best is carcinoma of the head of the pancreas with metastases to a node at the hilus of the liver. On the other hand, because this diagnosis does not satisfy the previous findings I am forced to make a second one of echinococcus disease of the liver, now inactive.

#### CLINICAL DIAGNOSES

Cholangitis and obstructive jaundice  
Lobar pneumonia

#### DR. MCKITTRICK'S DIAGNOSES

Carcinoma of pancreas with metastasis to hilus of liver  
Cholangitis  
Echinococcus disease of liver, inactive

#### ANATOMICAL DIAGNOSES

(Cyst of liver, cholangiectatic)  
(Chronic cholecystitis)  
(Cholelithiasis)  
Carcinoma of extrahepatic bile ducts with metastasis to regional nodes  
Suppurative cholangitis  
Hydrothorax, bilateral.  
Pulmonary atelectasis, right middle and both lower lobes  
Icterus

#### PATHOLOGICAL DISCUSSION

DR MALLORY: I do not know whether there is anyone in the audience who has had more experience with echinococcus disease than we have had in this laboratory and can tell us whether the first cyst was consistent with echinococcus disease. The echinococcus cysts that I have seen have all had

a very characteristic wall, consisting of a so-called chitinous membrane, which is readily recognizable. There was no trace of any membrane of that sort. The wall of the cyst consisted mostly of dense fibrous tissue, but after cutting a good many sections we finally found a few columnar epithelial cells which suggested to us that it probably was a dilated bile duct. As to why the stones should have been cystic, I have no explanation. The original cyst remains considerable of a mystery to us still. At the autopsy we found the obstruction of the common duct at the junction of the two hepatic ducts, as recorded in Dr Stewart's note describing the second operation. Sections through that area show carcinoma, whereas with the extensive dissection that is possible at the autopsy table we thought we could rule out cancer in the pancreas. There were nodes in the gastrohepatic ligament and near the head of the pancreas which contained tumor, but the pancreas itself was entirely free from tumor. So our final diagnosis was a primary carcinoma of the extrahepatic bile ducts. The liver at the time of autopsy was very large, weighed over 3000 gm, was studded with minute

abscesses and showed marked dilatation of all the intrahepatic bile ducts, in other words a characteristic picture of extensive cholangitis behind the point of obstruction.

DR AUBREY O HAMPTON: Were there any metastases to the lungs?

DR MALLORY: No.

DR HORATIO ROGERS: Do you think the black stools could have been caused by bleeding from the cancer in the bile ducts?

DR MALLORY: I remember one case in which melena was apparently proved to be due to a cancer within the bile ducts. I think the more likely explanation would be that it was due to extensive petechial hemorrhages in the bowel in a severely jaundiced patient. This patient did have a low prothrombin level.

DR GRANTLEY W TAYLOR: Did the cyst at the original operation reaccumulate?

DR MALLORY: It could not be recognized at autopsy. The space where it had been was occupied by a large abscess cavity, about 8 cm in diameter, which showed no characteristic lining of any sort.

COMMUNICATIONS should be addressed to the NEW ENGLAND JOURNAL OF MEDICINE, 8 Fenway Boston, Mass.

## IS THE MEDICAL PROFESSION OVERCROWDED?

It is sometimes claimed that the medical profession is overcrowded. The proponent of this claim is usually a member of the medical profession and the ground for the complaint is that there are many doctors, far too many, who are not able to make a comfortable living. If one employs in other fields the line of reasoning which has led to this conclusion one may well declare that the United States, not to speak of the earth, is overcrowded. It is an admissible hypothesis and it may prove after careful study to be sound for working purposes, but we want the facts, if facts there be, on which the hypothesis is predicated. The problem has not been subjected to the searching analysis which it deserves and satisfactory criteria for passing judgment have not been established. It is one of our 'vulgar errors,' as Sir

Thomas Browne might have said, to build our inductions on too narrow a foundation.

An obvious maladjustment in medicine and its social relations today is defective distribution of physicians. Still another defect, in the profession, is ignorance and lack of skill. Another defect, in society, is that the medical profession is not regarded with proper respect and confidence. Perhaps the profession as a whole gets about what it deserves—certainly the vogue of the cultist and of the patent-medicine vendor should not be passed over too lightly, with a sneer at the folly of mankind. It represents a difficult problem, to be approached in all seriousness; there is no short cut to a changed world. It would be a simple matter to wipe out tuberculosis or syphilis in a generation, if it were not for human nature.

One lesson from preventive medicine is plain to all: if we save infants, there will be more persons to die in youth or in middle or advanced age. Why do we think there should be need of fewer physicians now than there were fifty years ago just because of the automobile and the telephone? It may be that we are demanding and getting a far higher level of medical service than did our grandfathers, and for this we may need more rather than fewer physicians.

There are many persons of keen intellect and marked proclivities toward efficiency who admire the marvelous progress in mass production of material things and who, envisioning the vast amount of medical service needed for the people of the United States in terms of material aggregations, seek to introduce methods of material efficiency into the practice of medicine. They will fail to accomplish even what they desire for they forget human nature, and the limitations in medicine of this type of efficiency are soon reached. This does not mean that there is not room for improvement. On the contrary, improvement in the quality of medical service is the most urgent need of today.

It has been said that medical schools should decrease their enrollment because there are too many doctors. If they ought to become smaller, it is not for this reason. The size of a medical school should be determined primarily by the number

of students who can be educated there at the highest possible level of quality of education. This, one must remember, is not a fixed level.

From bare statistical comparisons with other countries one might conclude, as has been done, that the United States has too many doctors per thousand of population, and also by the same token, too many telephones, too many automobiles, too many bath tubs. It is a fact that no one knows how many physicians there should be in the United States and any arbitrary limitation might prove to be a serious mistake. Perhaps if there were better physicians, even more would be needed to care adequately for the population. Our health is far from perfect!

Every effort should be made to improve the quality of medical education, and hence the quality of medical service, by assisting medical schools to increase their facilities in every practicable way. If any school is found which refuses to come up to the generally accepted level for contemporary medical education and persists in giving its degree to candidates without reasonable qualification it should be forcibly reminded that it is failing in its duty to the public.

### PRESENT-DAY PSYCHIATRY

The Symposium on Mental Health held in December, 1938, at Richmond, Virginia, in conjunction with the American Association for the Advancement of Science, furnished an excellent summary of our modern thought on this difficult subject. The symposium, divided into six different sections, took up various aspects of the psychiatric problem in a way which had never been previously attempted. At the head of each section was a physician of outstanding importance in his field, and a summary of their conclusions, issued separately, forms an important document in the fight against mental disease.

Some of the points emphasized in this conference, although perhaps widely known, deserve to be brought again to the attention of the medical profession. The care of the mentally ill and the

advancement of research in psychiatry are two of the most important problems facing the medical profession. As one of the speakers pointed out, "despite the far-reaching advances in the treatment of the mentally ill in the past few years, patients enter mental hospitals in greater numbers than they go out, and we are faced with the prospect of a progressive increase in hospitalized mental disease." Thus the problem is one which is not getting smaller, and for a number of years to come it seems likely that more people rather than less will seek relief from their mental ills in properly equipped hospitals. Thus the better the service given, the more take advantage of it, until the time comes when the quality of the service is such that the disease begins to decrease, as it is gradually conquered. We appear to be far from that point in the evolution of psychiatric progress. Psychiatric research seems to be essential as "we need additional knowledge concerning the nature and causes of mental disease, which only sustained and systematic scientific investigation can give us." At the present time, in spite of the vast amount of money expended by private, state and federal funds, little vigorous research is carried on in mental hospitals, largely because of the inadequate staffs, the insufficient remuneration and a low clinical standard. Psychiatric research really should be a matter of public policy, for the public themselves are as much interested in this problem as are the physicians.

Another author, looking at the sources of mental disorder, pointed out that a large group of patients with mental disease are of the constitutional and hereditary type. Research in this matter has gone far enough to suggest certain remedial, hygienic and eugenic forms of treatment. Perhaps the most important suggestion comes in relation to the effort to make adequate and uniform marriage laws, thus preventing precipitous and ill considered matings. Along the same line is the suggestion of voluntary selective sterilization. Syphilis and alcohol, as other causes of mental disease, have already been fairly well attacked by a general program, which has the co-operation of all the

agencies involved in the problem. The lack of adequate nutrition, moreover, plays a role in mental disease much larger than ordinarily suspected by the average physician. In this land of plenty it is surprising to learn that a large part of the American population is not optimally nourished.

The problem, moreover, of the prevention and care of mental disease is closely allied to many social and economic aspects of our lives. Efforts are being made to conserve the values of family life by the proper placing of dependent children. Everything that tends, also, to increase the economic standard of the American family is undoubtedly a factor in the prevention of mental disease. Much has been done already by community organization and by federal aid. The value of the social-security project is certainly not to be minimized on the basis of the future mental health of the recipients.

Other research problems which interest the modern psychiatrist are those connected with cultural anthropology, social psychology and even political science. The more advanced statesmen are turning to psychiatry for help in some of their problems. Mention is made of the control of "integrative politics" by taking it over from those who lack insight and understanding of human needs. Attempts might be made to present the knowledge already gained in regard to psychiatric thought to aid "in the direction of human affairs and in countering the waves of propaganda and prejudice that block efforts at a scientific reform of our national life."

Finally, stress is laid on the fight against mental disease as a "totalitarian war in which all elements in the population must take their part. Propaganda must be employed, but what we want to propagate is the truth. It is the special role of those who are most closely associated with this special field of medicine to increase our body of knowledge as rapidly as possible, to give additional precision to the general principles which are gradually being outlined to bring the facts within this field of medicine into their natural relationship with other branches of science."

#### LACERATION OF THE CERVIX AND LOWER SEGMENT

Mrs. B., a thirty-year-old para II, entered the hospital January 7, 1938, at term and in active labor.

The family history was noncontributory. Her past history revealed an attack of bronchopneumonia in 1930 but no other medical diseases. In 1933 an appendectomy had been performed, and in 1935 she had had a complete amputation of the cervix for serious laceration resulting from her first delivery which was terminated by low forceps. She had had no abortions or miscarriages. Catamenia began at thirteen, were regular with a twenty-eight-day cycle and lasted four days without pain. Her last period was March 28, 1937, making her due for confinement January 2.

Physical examination showed the patient to be a well-developed and nourished woman. The heart was not enlarged, there were no murmurs. The lungs were clear and resonant, there were no rales. The blood pressure was 130 systolic, 80 diastolic. A postappendectomy scar was visible on her abdomen. Abdominal palpation showed a uterus at term, with a vertex presentation in the LOA position. The fetal heart rate was 130 in the left lower quadrant. The pelvic measurements were normal. The red-blood-cell count was 4,250,000 with a hemoglobin of 85 per cent (Tallqvist). The urine examination was negative.

Shortly after admission the membranes ruptured and the patient made rapid progress to full dilatation. An hour and a half after entry she was delivered normally of a 7 pound, 4 ounce, baby. After the birth of the baby there was more than a moderate amount of bright-red blood, and the placenta was immediately expelled. The bleeding continued after the birth of the placenta although the fundus was well contracted. Because of the amount of bleeding and because the fundus was well contracted, it was inferred that the bleeding must come from a laceration. In consequence the cervix was brought into view and a cervical rent was discovered on the left, which extended

\* A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

into the broad ligament. An attempt was made to suture this tear, and the vagina was packed tightly with sterile gauze. In spite of this, profuse bleeding continued. Intravenous glucose in saline was given, and prospective donors were summoned. The patient's pulse became alarmingly rapid and thready, her color became very poor, and her blood pressure dropped to 80 systolic, 60 diastolic. She quickly weakened from the loss of blood and died about forty minutes after the birth of the baby, before a transfusion could be given.

*Comment* This case of hemorrhage following normal labor was due to a considerable laceration of the cervix extending into the lower segment. The scar tissue resulting from a previous amputation of the cervix did not dilate. Scarred cervixes often tear but rarely in normal labor. The case was unique, too, in the amount of external hemorrhage, since lacerations of the lower segment are usually accompanied by little external bleeding. In such cases the diagnosis is made on the evidence of shock and hemorrhage without visible bleeding in a case in which the fundus remains well contracted after the birth of the placenta.

The attempt to stop the bleeding by suturing the torn cervix was unsuccessful. Undoubtedly a tear in one of the branches of the uterine artery was the cause of the bleeding. Immediate transfusion by replacing acute blood loss while further surgery, possibly hysterectomy, was resorted to might well have saved this patient's life. The routine grouping of patients, having a donor at hand and possibly the establishment of blood banks will make the handling of such cases efficient and undoubtedly save lives.

#### NOTICE TO APPLICANTS FOR FELLOWSHIP IN THE MASSACHUSETTS MEDICAL SOCIETY

The next meeting of the Board of Censors will be held in the various districts on Thursday, May 4.

Under recent changes in the by-laws, applications must be submitted early. The secretary of the district medical society should be consulted immediately for further information.

A S BEGG, *Secretary,*  
*Massachusetts Medical Society*

#### LEGISLATIVE NOTES

##### VOTE ON OSTEOPATHIC BILLS AND ANNUAL REGISTRATION

RETURN TO TUESDAY A. M., MARCH 7

H 985 Two osteopaths on board. Favor, 7, oppose, 1220, blank, 21.

H 986 Osteopath on approving authority. Favor, 31, oppose, 1195, blank, 22.

H 60 Annual registration. Favor, 759, oppose, 468, blank, 20.

Below is listed the progress in the Legislature of some of the bills in which the Massachusetts Medical Society is interested.

#### FAVOR

S 258 Bill relative to the meaning of the terms "rendering medical service," practice of medicine and holding oneself out as a practitioner of medicine and to exempt dentists, optometrists and chiropodists in certain cases from penalties provided for the unlawful practice of medicine. The bill was proposed by the Board of Registration in Medicine. It is favored by the Society with the addition of the following sentence at the end of Section 5A: Such treatment shall include examination of any secretion, excretion or discharge of the living body.

This bill was heard before the Committee on Public Health on February 9, but no report has yet been made.

H 59 Identical with S 258.

This bill was heard at the same time as S 258, but no report has yet been made.

H 60 Bill requiring annual licensing of qualified physicians. This bill was proposed by the Board of Registration in Medicine, and gives the necessary powers to the Board. The Council of the Massachusetts Medical Society voted to favor it by a vote of 114 to 34.

It was heard by the Committee on Public Health on February 9, but no report has yet been made.

H 61 Bill relative to the qualification for membership on the Board of Registration in Medicine. This bill allows any number of members to be members of one medical society.

The bill has been signed by the Governor.

H 72 Bill providing for the care of certain infants prematurely born. It was proposed by the Department of Public Health, and corrects defects in the previous bill.

It has been passed by the House and referred back to the Committee on Ways and Means. Ways and Means reports it ought to pass with an amendment.

H 73 Bill providing for supplementary reporting of congenital deformities and birth injuries in infants. The bill was proposed by the Department of Public Health and requires that supplementary reports be sent to this department.

This bill was heard before the Committee on Public Health and favorably reported to the house.

H 74 Bill requiring the clerk or registrar in each city or town to give to persons who file notice of intention of marriage suitable information concerning gonorrhea and syphilis. The bill was proposed by the Department of Public Health and it contains no compulsion.

This bill will be heard by the Committee on Public Health, on March 28.

H 75 Bill making various changes in the laws relating to foods and drugs. The bill was proposed by the Department of Public Health in order to bring the state law into line with the new federal act.

It will be heard by the Committee on Public Health, on March 16.

*H 670* Bill providing for the issuance of certificates of approval of bacteriological laboratories by the Department of Public Health. The bill was proposed by the Massachusetts Public Health Association and is similar to the one favored by the Massachusetts Medical Society last year.

It will be heard by the Committee on Public Health, on March 23.

*H 852* Bill requiring licensing of hospitals, convalescent homes and nursing homes. This bill was proposed by the Massachusetts Central Health Council and provides for the Department of Public Health to set up certain standards of health and enforce them.

It was heard by the Committee on Public Health on February 2, but there is to be another hearing later.

*H 1407* Bill prohibiting aliens from practicing medicine. This bill was proposed by Rep. Vaughan and is poorly written. It provides that no license be granted to an alien until his first papers have been filed but allows certain very broad exceptions.

This bill will be heard by the Committee on Public Health, on March 14.

#### OPPOSE

*H 287* Bill providing for a marriage protection law by requiring a physician's examination and certificate before issuance of marriage licenses. This bill was proposed by Rep. Cutler and it needs major revision before being satisfactory.

It will be heard before the Committee on Public Health, on March 28.

*H 551* Bill requiring that notices of intention of marriage shall be accompanied by a physician's certificate that neither party is infected with syphilis. This bill was proposed by Dr. William Frankman and also needs major revision before being satisfactory.

It has been assigned to the Committee on Public Health for a hearing, on March 28.

*H 758* Bill providing authority to the Board of Registration of Nurses to limit further training of nurses of all classes and attendants under certain conditions. The bill was proposed by Miss Josephine E. Thurlow but is against public policy.

It was heard by the Committee on Public Health on February 2 and again on March 7.

*H 759* Bill providing for training and licensing of first class bedside nurses. This bill was proposed by Miss Josephine E. Thurlow, but is against public policy.

It was heard by the Committee on Public Health on February 2 and again on March 7.

*H 858* Bill regulating the practice of nursing. This bill was proposed by the Massachusetts State Nurses Association, and while it is better than last year's bill, some of last year's defects are still present.

It was heard by the Committee on Public Health on February 2 and again on March 7.

*H 985* Bill requiring doctors of medicine and doctors of osteopathy on the Board of Registration in Medicine. This bill was proposed by the Massachusetts Osteopathic Association and would put two osteopathic physicians on the Board.

It was heard before the Committee on Public Health on February 9, but no report has yet been made.

*H 986* Bill providing for a doctor of medicine and a doctor of osteopathy on the Approving Authority and the

status of approvals by the American Medical Association and the American Osteopathic Association. This bill was proposed by the American Osteopathic Association, it weakens the Approving Authority.

This bill was heard February 9 by the Committee on Public Health, but it has not yet made a report.

*H 1401* Bill providing that certificates of vaccination or non-vaccination shall no longer be required as a prerequisite to the attendance of any child in public schools. This is a typical anti-vaccination bill.

It will be heard before the Committee on Public Health on April 4.

*H 1898* Bill providing for the establishment and administration of a system of health insurance. This bill was proposed by the State Industrial Council of the Congress of Industrial Organization (CIO) and means complete state insurance with a  $4\frac{1}{2}$  per cent pay roll tax. It represents real regimentation of physicians.

It will be heard by the Committee on State Administration on March 15.

#### CHANGE IN COMMITTEE MEMBERSHIP

Dr. Charles A. Robinson, of the Suffolk District Medical Society, has resigned as a member of the Committee on State and National Legislation. His resignation has been accepted by Dr. Frothingham, who appointed on March 1, Dr. Earle M. Chapman, of Suffolk District, as a member of the committee pro tem.

#### MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning March 13.

#### BARNSTABLE

Sunday, March 19, at 4 00 p m, at the Cape Cod Hospital, Hyannis. Subject—Syphilis Latent syphilis—diagnosis and treatment. Instructor C. Guy Lane. Donald E. Higgins, *Chairman*.

#### BERKSHIRE

Thursday, March 16, at 4 30 p m, at the House of Mercy Hospital, Pittsfield. Subject—Anemia. Modern methods in diagnosis and treatment of blood dyscrasias. Instructor Greene FitzHugh. Melvin H. Walker, Jr., *Chairman*.

#### BRISTOL NORTH

Thursday, March 16, at 4 00 p m, at the Morton Hospital, Taunton. Subject—Gonorrhea. Modern treatment of gonorrhea. Instructor George C. Prather. Lester E. Butler, *Chairman*.

#### BRISTOL SOUTH (Fall River Section)

Tuesday, March 14, at 4 00 p m, at the Union Hospital, Fall River. Subject—Bright's Disease and Hypertension. Evaluation of new therapy. Instructor Laurence B. Ellis. Howard P. Sawyer, *Chairman*.

## FRANKLIN

Wednesday, March 15, at 8 00 p m, at the Franklin County Public Hospital, Greenfield Subject—Bleeding in the Third Trimester of Pregnancy Instructor M V Kappius Halbert G Stetson, *Chairman*

## HAMPTDEN

Thursday, March 16, at 4 00 p m. at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8 00 p m, in the Outpatient Department of the Skinner Clinic, Holyoke Hospital, Holyoke Subject—Syphilis Latent syphilis—diagnosis and treatment. Instructor William P Boardman George L. Schadt, *Chairman*

## MIDDLESEX EAST

Tuesday, March 14, at 4 00 p m., at the Melrose Hospital (Colby Hall), Melrose. Subject—Syphilis Latent syphilis—diagnosis and treatment. Instructor Rudolph Jacoby Walter H. Flanders, *Chairman*

## MIDDLESEX NORTH

Thursday, March 16, at 4 30 p m, at St. John's Hospital, Lowell Subject—The Toxemias of Pregnancy Instructor Foster S Kellogg William S Lawler, *Chairman*

## MIDDLESEX SOUTH

Tuesday, March 14, at 5 00 p m., at the Cambridge Hospital, 330 Mt. Auburn Street, Cambridge. Subject—Anemia Modern methods in diagnosis and treatment of blood dyscrasias Instructor George R. Minot. Alexander A. Levi, *Chairman*

## SUFFOLK

Thursday, March 16, at 4 30 p m, in John Ware Hall, Boston Medical Library, 8 Fenway, Boston Subject—Bright's Disease and Hypertension. Instructor James P O'Hare. Reginald Fitz, *Chairman*

## MISCELLANY

## NOTE

The Henry Asbury Christian Prize, one of the outstanding honors at the Harvard Medical School, has been awarded to Henry Swann, II, of Denver, Colorado, a fourth year student, it was announced today The prize is awarded to the student in the fourth year class who has displayed diligence and notable scholarship and offers promise for the future. The award was established in 1937 in honor of Dr Henry A. Christian, Hersey Professor of the Theory and Practice of Physics Mr Swann graduated from Williams College in 1935

In addition, the following awards, totaling \$1700, for the current academic year, were made to thirteen freshmen at the medical school, as follows David William Cheever scholarship to Richard V Ruddell, of Elizabeth, New Jersey, Charlotte Greene scholarship to Raymond O Olson, of Providence, Rhode Island, George Haven scholarships to William B Ayers, of Bethlehem, Pennsylvania, Frank A Bautze, of Jamaica Plain, Martin J Bellinger, of Miami, Arizona, John S Chambers, Jr, of Lexington, Kentucky, Burdick G Clarke, of Winnetka, Illinois, Hale H. Cook, of Yonkers, New York, Norman M. Fellows, of Claremont, California, William K. Hall, of Springfield, Missouri, William J Lahey, of East Hartford, Connecticut, Lindley B Reagan, of Poughkeepsie, New York and John Q U Thompson, of Jacksonville, Florida.

## CORRESPONDENCE

## THE NEW BLUE-CROSS CONTRACT

*To the Editor* In the wording of the policy of the Associated Hospital Service Corporation, or Blue Cross, an attempt was made to specify that subscribers who went to a hospital just for diagnosis and not for treatment should not have their bills paid under the terms of the contract For this purpose the term 'periodic health examination' was used in the paragraph which enumerated the service that the contract does not cover Of course, it is a difficult line to draw in trying to separate cases that enter a hospital for diagnosis or for treatment, and in order to clarify this point the directors of the Blue Cross have voted to use the following rule in endeavoring to reach a decision whether the patient enters the hospital just for diagnosis or for treatment

On motion duly seconded it was voted that the Associated Hospital Service Corporation is willing to pay the bills of patients with illnesses or for diagnostic procedure, which, per se, require hospitalization in the opinion of the admitting physician, and furthermore, in interpreting this general policy should be that the admission to a hospital for diagnosis should be done only where the symptoms are those of acute illness

It is not the intention of the Blue Cross to interfere with patient physician relations or with the physician hospital relations It is the aim of the directors to have the Blue Cross provide only those services which are considered generally as hospital services Therefore, physicians should not attempt to hospitalize subscriber patient for purely diagnostic x rays which could be performed in a doctor's office. If a patient is acutely ill and in the opinion of the attending physician that patient should be admitted to the hospital for diagnostic purposes, then this is a service which the Blue Cross provides Therefore whether or not a patient is hospitalized is entirely up to the physician. If, in his opinion, the patient is not acutely ill, and x rays are needed, the patient should be referred to a roentgenologist who has adequate equipment to provide the required services

The new subscriber contract provides for anesthesia if administered by a salaried employee of the hospital Only in this way can anesthesia be considered as a hospital service. If anesthesia is administered by a non salaried anesthetist then it becomes a medical service and it is the avoidance of offering medical services which the Blue Cross has attempted in this new contract.

Practically every non profit hospital service plan in the country that provides x ray services offers unlimited service, but the basis of payment is on that of the hospital's average per-diem cost. In all cases no specific payments are made for anesthesia, they are included only if administered by a salaried employee of the hospital In order that the Blue Cross may have a better reciprocal understanding with the other plans approved by the American Hospital Association it is our desire to bring our contract in line.

Associated Hospital Service Corporation of Massachusetts,  
R. F. CAHALANE, *Executive Director*

21 Milk Street,  
Boston

## NOTICES

## REMOVAL

CARL A. DE SIMONE, M.D., announces the removal of his office to 3 Sparhawk Street, Brighton Telephone STAdium 428

JOSEPH H. SHORTELL, M.D., announces the removal of his office to 478 Commonwealth Avenue, Boston Telephone KENmore 4246

## AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

The general oral, clinical and pathological examinations for all candidates, Part 2 examinations will be held as follows: Group A, Saturday and Sunday, May 13 and 14; Group B, Monday and Tuesday, May 15 and 16, immediately prior to the annual meeting of the American Medical Association, at St. Louis, Missouri. Notice of the time and place of these examinations will be forwarded to all candidates well in advance of the examination dates.

Candidates for re-examination in Part 2 (Groups A and B) must request such re-examination by writing the secretary's office before March 15. Candidates who are required to take re-examinations must do so before the expiration of three years from the date of their first examination.

The annual dinner meeting of the board, to which all diplomates and candidates are invited, as well as wives and others interested in the work of the board, will be held on Wednesday evening, May 17, following the close of the examinations.

Application for admission to the Group A, May, board examinations must be on file in the secretary's office not later than March 15. Application blanks and booklets of information may be obtained from Dr. Paul Titus, secretary, 1015 Highland Building, Pittsburgh (6), Pennsylvania.

## MEDICAL CLINIC AT THE PETER BENT BRIGHAM HOSPITAL

At 3 30 p.m. on Thursday, March 16, in the amphitheater of the Peter Bent Brigham Hospital, Dr. Robert T. Monroe will give a medical clinic. Practitioners and medical students are cordially invited to attend.

## SIR WILLIAM OSLER HONORARY SOCIETY OF THE TUFTS COLLEGE MEDICAL SCHOOL

The annual lecture of the Sir William Osler Honorary Society of the Tufts College Medical School will be given by Dr. Soma Weiss on Friday evening, March 17, at 8 00, in the Beth Israel Hospital Auditorium, Boston.

Dr. Weiss will speak on 'The Medical Student Before and After Graduation.'

LEONARD M. KLEIN, *Secretary*

## NEW ENGLAND SOCIETY OF PHYSICAL MEDICINE

The regular meeting of the New England Society of Physical Medicine will be held at Hambury Hall, Ring Sanatorium and Hospital, Arlington Heights, on Wednesday evening, March 15, at 8 00. At 6 45 a buffet supper

will be served to the members and guests in the main dining room of the Sanatorium.

## PROGRAM

Combined Physical Therapy and Motivation in the Treatment of the Psychoses. Dr. Abraham Myerson. Discussion by Drs. Kenneth B. Tillotson and Curtis T. Prout.

All members of the medical profession are cordially invited to attend.

WILLIAM D. McFEE, M.D., *Secretary*

## BOSTON DOCTORS SYMPHONY ORCHESTRA

Rehearsals of the newly organized Boston Doctors Symphony Orchestra, conducted by Nicolas Slonimsky, are held every Thursday evening at 7 30 at Hampton Court Hotel, 1223 Beacon Street, Brookline.

Membership is still open. All physicians, dentists and medical and dental students who are interested should communicate with Dr. Julius Loman, Pelham Hall Hotel, Brookline (BEA 2430).

## SUFFOLK DISTRICT POSTGRADUATE EXTENSION COURSE

The Suffolk District Medical Society will offer a postgraduate extension course on eight Thursday afternoons at 4 30 o'clock, beginning March 16, 1939. The meetings will be held in John Ware Hall, Boston Medical Library, 8 Fenway, Boston. The first talk is as follows:

March 16. Bright's Disease and Hypertension. Instructor, Dr. James P. O'Hare.

Any registered physician is welcome to these sessions; registration is free. You can be on call (telephone, Commonwealth 2800).

REGINALD FITZ, *Chairman*  
LEROY E. PARKINS,  
JOHN F. CORREA, JR.,  
CHARLES MELONI,  
HAROLD L. MUSGRAVE,  
JOHN P. MONKS, *Secretary*  
Postgraduate Committee.

## HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held on Tuesday, March 14, in the amphitheater of the Peter Bent Brigham Hospital (Shattuck Street entrance), at 8 15 p.m.

## PROGRAM

Presentation of cases.

How Does One Study the Cancer Problem? By investigators of the Collis P. Huntington Memorial Hospital.

Medical students and physicians are cordially invited to attend.

ROBERT M. ZOLLINGER, M.D., *Secretary*

## FRANKLIN

Wednesday, March 15, at 8 00 p m, at the Franklin County Public Hospital, Greenfield Subject—Bleeding in the Third Trimester of Pregnancy Instructor M V Kappius Halbert G Stetson, *Chairman*

## HAMPDEN

Thursday, March 16, at 4 00 p m at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8 00 p m, in the Outpatient Department of the Skinner Clinic, Holyoke Hospital, Holyoke Subject—Syphilis Latent syphilis—diagnosis and treatment. Instructor William P Boardman George L. Schadt, *Chairman*

## MIDDLESEX EAST

Tuesday, March 14, at 4 00 p m, at the Melrose Hospital (Colby Hall), Melrose. Subject—Syphilis Latent syphilis—diagnosis and treatment. Instructor Rudolph Jacoby Walter H. Flanders, *Chairman*

## SUFFOLK

Thursday, March 16, at 4 30 p m, in John Ware Hall, Boston Medical Library, 8 Fenway, Boston Subject—Bright's Disease and Hypertension Instructor James P O'Hare. Reginald Fitz, *Chairman*

## MISCELLANY

## NOTE

The Henry Asbury Christian Prize, one of the outstanding honors at the Harvard Medical School, has been awarded to Henry Swann, II, of Denver, Colorado, a fourth-year student, it was announced today. The prize is awarded to 'the student in the fourth year class who has displayed diligence and notable scholarship and offers promise for the future.' The award was established in 1937 in honor of Dr. Henry A. Christian, Hersey Professor of the Theory and Practice of Physic. Mr. Swann graduated from Williams College in 1935.

In addition, the following awards, totaling \$1700, for the current academic year, were made to thirteen freshmen at the medical school, as follows: David William Cheever scholarship to Richard V. Riddell, of Elizabeth, New Jersey; Charlotte Greene scholarship to Raymond O. Olson, of Providence, Rhode Island; George Haven scholarships to William B. Ayers, of Bethlehem, Pennsylvania; Frank A. Bautze, of Jamaica Plain; Martin J. Bellinger, of Miami, Arizona; John S. Chambers, Jr., of Lexington, Kentucky; Burdick G. Clarke, of Winnetka, Illinois; Hale H. Cook, of Yonkers, New York; Norman M. Fellows, of Claremont, California; William K. Hall, of Springfield, Missouri; William J. Lahey, of East Hartford, Connecticut; Lindley B. Reagan, of Poughkeepsie, New York; and John Q. U. Thompson, of Jacksonville, Florida.

## CORRESPONDENCE

## THE NEW BLUE-CROSS CONTRACT

*To the Editor* In the wording of the policy of the Associated Hospital Service Corporation, or Blue Cross, an attempt was made to specify that subscribers who went to a hospital just for diagnosis and not for treatment should not have their bills paid under the terms of the contract. For this purpose the term "periodic health examination" was used in the paragraph which enumerated the services that the contract does not cover. Of course, it is a difficult line to draw in trying to separate cases that enter a hospital for diagnosis or for treatment, and in order to clarify this point the directors of the Blue Cross have voted to use the following rule in endeavoring to reach a decision whether the patient enters the hospital just for diagnosis or for treatment:

On motion duly seconded it was voted that the Associated Hospital Service Corporation is willing to pay the bills of patients with illnesses or for diagnostic procedure, which, per se, require hospitalization in the opinion of the admitting physician, and furthermore, in interpreting this the general policy should be that the admission to a hospital for diagnosis should be done only where the symptoms are those of acute illness.

It is not the intention of the Blue Cross to interfere with patient-physician relations or with the physician-hospital relations. It is the aim of the directors to have the Blue Cross provide only those services which are considered generally as hospital services. Therefore, physicians should not attempt to hospitalize subscriber patients for purely diagnostic x-rays which could be performed in a doctor's office. If a patient is acutely ill and in the opinion of the attending physician that patient should be admitted to the hospital for diagnostic purposes, then this is a service which the Blue Cross provides. Therefore, whether or not a patient is hospitalized is entirely up to the physician. If, in his opinion, the patient is not acutely ill, and x-rays are needed, the patient should be referred to a roentgenologist who has adequate equipment to provide the required services.

The new subscriber contract provides for anesthesia if administered by a salaried employee of the hospital. Only in this way can anesthesia be considered as a hospital service. If anesthesia is administered by a non-salaried anesthetist then it becomes a medical service and it is the avoidance of offering medical services which the Blue Cross has attempted in this new contract.

Practically every non-profit hospital service plan in the country that provides x-ray services offers unlimited service, but the basis of payment is on that of the hospital's average per-diem cost. In all cases no specific payments are made for anesthesia; they are included only if administered by a salaried employee of the hospital. In order that the Blue Cross may have a better reciprocal understanding with the other plans approved by the American Hospital Association it is our desire to bring our contract in line.

Associated Hospital Service Corporation of Massachusetts,  
R. F. CAHALANE, *Executive Director*

#### THE X-RAY TREATMENT OF CANCER IN SMALL COMMUNITIES\*

FREDERICK W O'BRIEN, M.D.†

BOSTON

IT IS a truism that surgery, radium and x-ray, alone or in conjunction, may cure some of the varied manifestations of malignant disease commonly grouped under the inclusive term of cancer. At the same time it is recognized that special training, experience and judgment are required in order to utilize these curative agents successfully.

This special training is not obtained readily outside of large metropolitan hospitals, where segregated surgery may be practiced and radiation methods evolved on the basis of large series of cases studied from many angles. Where segregated surgery is not the vogue and cases are assigned in rotation, an individual surgeon during a year may operate on only a single case of cancer of the breast whereas 30 or more such cases are operated on yearly in the hospital. This shows the importance of the cancer institute, where cancer of certain anatomic regions and systems is operated on in the same manner by assigned surgical groups for a period of years, in order to obtain satisfactory data on which to predicate practical application of the knowledge thus acquired.

So too with irradiation. The methods of application are best developed at a cancer institute or large metropolitan hospital with an ample supply of radium for external and interstitial use, adequate x-ray apparatus capable of utilization over a wide range of potentials and an abundance of clinical material under a director of radiation therapy, who has the services of one or more competent physicists and the close co-operation of a tumor-clinic staff.

Fundamental as is intensive research in these institutes as to the cause of cancer, its possible con-

trol and its cure by natural or synthetic agents, surgery and irradiation continue in the forefront as the therapeutic mainstay. The number of cancer research centers now functioning in America is limited. The cost of increasing their number seems at present prohibitive despite our vaunted national wealth. Therefore, even though it is desirable for all cancer cases to have the benefit of study in such a highly specialized institute, it is not yet feasible. The cancer institute, however, is meeting the situation by training graduate physicians in clinical pathology, surgery and irradiation; they go forth each year, a small but an increasing group, some of them settling permanently in the small communities, and thus assuring sufferers from cancer outside of metropolitan centers intelligent care.

These special institutions have been functioning long enough in the study and treatment of malignant disease to have promulgated definite notions about the indications for and the limitations of surgery and irradiation in cancer therapy. This material has appeared in special monographs and current medical journals and is available for those who are interested.

The pathologist has taught the surgeon and the radiation therapist to evaluate the natural history of the tumor he is to treat. The informed surgeon no longer operates merely because a case is technically operable, the radiologist knows better when and where to irradiate. Thanks to the physicist, who has given him a standard of mensuration, data on erythema, tissue recovery rate and on ionization in the tissues, the radiation therapist knows how to irradiate, and understands some of the reasons for x-ray treatment. The treatment of cancer is no more a matter of envious competition but one of willing co-operation.

It is now fairly well agreed that high-voltage

## BOOK REVIEW

*Immune Blood Therapy of Tuberculosis with Special Reference to Latent and Masked Tuberculosis* Joseph Hollos 197 pp New York, 1938 \$2.00

The medical world is still looking for a better treatment of pulmonary tuberculosis. The author of the present book thinks he has found it in the use of immune blood. For many years he has tried to convince the doctors abroad and in this country that he is right, but his efforts have not met with success. Since coming to New York City more than twelve years ago his book has been turned down by seven American publishers and is now published by the author himself.

The 'immune blood' is obtained from rabbits which have been infected with a symbiotic culture of human and bovine bacilli. The blood taken from the veins of several immunized rabbits is diluted with 0.5 per cent phenol salt solution containing 0.5 per cent lactic acid. The blood [entirely hemolyzed in this way] is freed from albumin and diluted 1:100,000. This yellowish, clear liquid, slightly acid and protein free, is the original immune-blood. This blood is then further diluted in various strengths and is either rubbed into the skin or given subcutaneously. Dilution X is 1:10,000,000,000 dilution of the original immune-blood.

One could have no quarrel with the trial of such a product under proper conditions, but the 36 cases of tuberculosis which the author presents and in which the material was used for treatment are not at all convincing. The author's case is greatly weakened by the last half of the book in which he takes up neurasthenia, rheumatism, thyrotoxicosis, dementia praecox, epilepsy, dysmenorrhea, disturbances of the digestive system, and other symptom complexes including cholecystitis, appendicitis, leukorrhea, coryza, asthma, neuralgia and psoriasis. He maintains that because these cases improved while he was giving them immune blood therapy all such conditions are in reality instances of masked tuberculosis.

### THE X-RAY TREATMENT OF CANCER IN SMALL COMMUNITIES\*

FREDERICK W. O'BRIEN, M.D.†

BOSTON

IT IS a truism that surgery, radium and x-ray, alone or in conjunction, may cure some of the varied manifestations of malignant disease commonly grouped under the inclusive term of cancer. At the same time it is recognized that special training, experience and judgment are required in order to utilize these curative agents successfully.

This special training is not obtained readily outside of large metropolitan hospitals, where segregated surgery may be practiced and radiation methods evolved on the basis of large series of cases studied from many angles. Where segregated surgery is not the vogue and cases are assigned in rotation, an individual surgeon during a year may operate on only a single case of cancer of the breast whereas 30 or more such cases are operated on yearly in the hospital. This shows the importance of the cancer institute, where cancer of certain anatomic regions and systems is operated on in the same manner by assigned surgical groups for a period of years, in order to obtain satisfactory data on which to predicate practical application of the knowledge thus acquired.

So too with irradiation. The methods of application are best developed at a cancer institute or large metropolitan hospital with an ample supply of radium for external and interstitial use, adequate x-ray apparatus capable of utilization over a wide range of potentials and an abundance of clinical material under a director of radiation therapy, who has the services of one or more competent physicists and the close co-operation of a tumor-clinic staff.

Fundamental as is intensive research in these institutes as to the cause of cancer, its possible con-

trol and its cure by natural or synthetic agents, surgery and irradiation continue in the forefront as the therapeutic mainstay. The number of cancer research centers now functioning in America is limited. The cost of increasing their number seems at present prohibitive despite our vaunted national wealth. Therefore, even though it is desirable for all cancer cases to have the benefit of study in such a highly specialized institute, it is not yet feasible. The cancer institute, however, is meeting the situation by training graduate physicians in clinical pathology, surgery and irradiation; they go forth each year, a small but an increasing group, some of them settling permanently in the small communities, and thus assuring sufferers from cancer outside of metropolitan centers intelligent care.

These special institutions have been functioning long enough in the study and treatment of malignant disease to have promulgated definite notions about the indications for and the limitations of surgery and irradiation in cancer therapy. This material has appeared in special monographs and current medical journals and is available for those who are interested.

The pathologist has taught the surgeon and the radiation therapist to evaluate the natural history of the tumor he is to treat. The informed surgeon no longer operates merely because a case is technically operable; the radiologist knows better when and where to irradiate. Thanks to the physicist, who has given him a standard of measurement, data on erythema, tissue recovery rate and on ionization in the tissues, the radiation therapist knows how to irradiate, and understands some of the reasons for x-ray treatment. The treatment of cancer is no more a matter of envious competition but one of willing co-operation.

It is now fairly well agreed that high voltage

†Preceptor of Radiology, Tufts College Medical School, visiting roentgenologist, Boston City Hospital.

x-rays, in the neighborhood of 200,000 volts, are probably adequate in the treatment of cancer amenable to x-ray therapy. The technic for the utilization of such high voltages has been well worked out as to filtration, distance, size of portals, surface and depth doses, time in relation to tissue effects, and end results, so that any trained radiologist can apply them.

If one can kill a third of all cancers of the breast by using 200,000 volts, it has been asked, why not use 1,000,000 volts and kill them all? Unfortunately, this is not a matter of arithmetical progression, there is more in cancer cure by irradiation than the mere magnitude of the potential. One argument often advanced for ultra-high-voltage x-rays is the greater depth dose which can be obtained by their use, but one does not always cure superficial cancer where the depth dose is presumably of little account.

So far as is known, it is absorbed radiation that produces biologic change. The shorter the wave length, the more penetrating is the ray. It is conceivable that radiation could be so penetrating, of such short wave length, that it would not be absorbed appreciably where most needed, this is in a measure what happens under certain conditions when 1,000,000-volt x-rays are used in treating the human body.

Quimby<sup>1</sup> demonstrated long ago, employing 200,000-volt rays and a 0.5 mm copper filter, that increasing the distance from 50 cm to 70 cm increased the relative depth dose even more than would result from a doubling of the voltage. However, if filtration of the order of 5 mm of copper is indicated, this would be uneconomical in certain 200,000-volt setups because of the lengthened duration of treatment. This disadvantage can be overcome by using ultra-high voltage of the medium range (400,000 to 500,000 volts). While the relative depth dose will not be appreciably greater than with 200,000 volts, the total dose that one may give with voltages of this higher range may be greater than can be given with 1,000,000-volt x-rays, since the dose at the surface of exit is not increased in proportion and the use of relatively large cross-fire portals is not thereby limited. Another practical factor to be considered is that with ultra-high-voltage therapy, while one is able to deliver more to the depths of thick parts than with 200,000-volt rays, the normal tissue surrounding the neoplasm receives the same increased dosage.

Indeed, the physicist describes voltages of 500,000 to 1,000,000 as modest voltages. Coolidge<sup>2</sup> recently stated that the range of an impulse generator employing the Marx circuit had been carried to 10,000,000 volts, and that it would apparently be

a perfectly simple engineering and manufacturing undertaking to build one for several times this voltage. Brasch and Lange in Germany have already used the impulse generator, together with a novel type of gas tube, for voltages up to 2,400,000. But there is a vast hinterland between such an engineering accomplishment and its practical application in cancer therapy.

Of greater importance than all theoretical considerations regarding ultra-high voltages is their clinical effect. Any clinic that has had competent experience with ultra-high-voltage x-ray therapy has been most diffident in reporting unfortunate sequelae, and distrustful even of reputed benefits.

Mudd, Emery and Levi,<sup>3</sup> who in 1930 began a clinical study of the effect of ultra high voltage x-rays on inoperable carcinoma, report that irradiated carcinoma of the prostate is a disease which sometimes progresses slowly, so that the palliation achieved with 1,000,000-volt therapy is difficult to evaluate, that results in bladder carcinoma have not been reassuring, that results in rectal carcinoma have been disappointing, that in late stages of cancer of the breast there is little or no additional advantage in supervoltage therapy as against adequate irradiation with 200,000-volt rays, and that in carcinoma of the larynx and pharynx 200,000-volt rays provide sufficient ionization in the tumor-bearing regions involved. In fairness to them it should be said that many of their cases were not only inoperable but hopeless from the beginning. Doubtless with more hopeful cases to treat and surer knowledge of technic their results will improve. This does not mean that there is no place in the cancer institute for ultra-high voltage x-ray generators, but it does mean that there is no justification for considering such generators as any thing more than experimental, and as yet unsuitable for general clinical use.

If this be true, treatment of cancer by x-ray in small communities becomes a much more practical matter. With a proper physical setup, a 200,000-volt machine and a trained radiologist, it is not necessary to send patients on a long journey to a metropolitan centre to obtain x-ray therapy which can be had and applied intelligently in the home community.

It may be instructive to examine the situation in Massachusetts outside of Metropolitan Boston. High-voltage x-ray equipment suitable for cancer therapy is found in Cambridge, Newton, Salem, Beverly, Lowell, Quincy, Brockton, Fall River, New Bedford, Norfolk, Worcester, Gardner, Springfield, Westfield and Pittsfield, so that no one, with the exception of those living along the tip of the Cape, need travel much more than

twenty-five miles for adequate care. The non-ambulant patient can be cared for comfortably since most of the apparatus is in hospitals.

To be sure, the possession of a high-voltage x-ray machine is not enough. That such a powerful agent for good or ill may be utilized as it should be, is now assured through the operation of the American Board of Radiology, which certifies on examination those qualified to practice x-ray therapy. I am happy to record that everyone in Massachusetts operating high-voltage equipment has been so certified, so that it would appear that the cancer patient in Massachusetts in need of this form of therapy may be treated adequately in our small communities.

Future advance in the x-ray treatment of cancer will probably depend on more certain knowledge of the biologic effects of radiation. Professor Crowther<sup>4</sup> says in a recent review that the first striking feature of any extended survey of the subject is the extraordinary difference shown by different tissues to the action of radiation. Mitosis is inhibited in a tissue culture by a dose of 120 r, but 13,000 r is required to produce even a delayed lethal effect. Apparently living material of any kind can be killed by a massive dose of radiation of the order of 100,000 r and upward. It is not surprising, Crowther adds, that a tissue culture can be killed by a dose of 100,000 r. What is surprising is that profound biologic effects can be produced in the same tissue with something like one thousandth of this dose.

The direct effect produced by the absorption of x-rays is ionization, upon which the biologic effect perhaps wholly depends, however long may be the chain that binds them. Ionization appears to be independent of wave length. The total ionization for equal intensities is probably the same whatever the wave length. Millikan,<sup>5</sup> however, says that the slower a negative electron moves, the more it is susceptible to deflection and the more frequently does it ionize the molecules through which it passes. Webster<sup>6</sup> points out that the short comma tracks produced by x-rays give rise within cells to more ionization per micron than do the longer tracks produced from the primary beam of ultra-high voltage and gamma rays. He says further that most biological experiments appear to show conclusively that if time and space distribution and intensity remain constant, the wave length is of little or no consequence. This is so with skin, lymph nodes, tumor cells, eggs and gene mutations.

Rather too much emphasis, I believe, has been placed on depth dose and lethal dose in cancer radiation therapy, and not enough on the normal physiologic response of the body economy through

which modification of structure is brought about. This is an important link in the chain that connects biologic effect with ionization. There is an axiom in forensic medicine to the effect that there must be a suitable correlation between the weapon employed and the injury received. Until such a suitable correlation between ultra-high-voltage radiation and its effect has been demonstrated, the physician in the small community may feel confident, and may assure his cancer patient, that high-voltage x-rays of about 200,000 volts are adequate for the treatment of cancer, and that ultra-high-voltage x-rays produced by 1,000,000-volt generators continue to remain in the realm of experimental research.

#### DISCUSSION

DR. RICHARD DRESSER, Boston. I have been much interested in Dr. O'Brien's comments on supervoltage radiation, that is on the effect of x rays produced at potentials greater than the usual 200,000 volts. When I began my work in radiation therapy in Boston some fifteen years ago there were only two machines in New England operating at this voltage, one at the Huntington Hospital and one at the Massachusetts General Hospital. This type of radiation was viewed with much skepticism both by radiologists and by the general profession. (It is an excellent scientific attitude to be skeptical of anything new until its worth has been proved.) Today there are more than a dozen 200,000-volt machines in operation in the hospitals of Greater Boston, and as many more have been installed in private offices. Radiologists are attacking the problem of therapy with increasingly greater enthusiasm and increased knowledge, and excellent work is being done, not only in Boston but in many of the small communities.

Today no one doubts the value of 200,000-volt radiation in the treatment of a great variety of malignant conditions. However, x rays produced at lower potentials still have their place in the therapy of many superficial conditions, both malignant and benign. It is my belief that supervoltage radiation is now in the same stage of development that 200,000-volt therapy was fifteen years ago. I am certain that the shorter, more penetrating wave lengths derived from the higher voltages will be found to be more effective in the treatment of certain neoplasms, particularly those which are deep-seated, but that supervoltage radiation will not be used to the complete exclusion of low voltage x rays.

The advantages of supervoltage radiation which we have observed in our experience of a year and a half are as follows. In the first place there is a greater tolerance of the skin to shorter wave lengths. It is therefore unnecessary to produce the severe erythemas which are

so frequently unavoidable with 200,000 volt treatment. Secondly, it is possible to deliver larger amounts of radiation to the deeper portions of the body. This is particularly true when small portals of entry are used. Thirdly, there is less general reaction—so-called roentgen sickness. Fourthly, the amount of radiation delivered below the surface is relatively independent of the size of the portal of entry. It is common practice with 200,000-volt radiation to use large portals of entry in order to increase the depth dose. This means irradiation of much normal tissue, which is unnecessary and even harmful. At higher voltages the portal of entry can be limited to cover only the disease-bearing area, without appreciable effect on the amount of radiation delivered to the tumor. Fifthly, there is possibly a selective action of the shorter wave lengths on neoplastic tissue, but this is still a moot point. Sixthly, it has been our observation that immediate regression of certain deep-seated neoplasms is more probable following supervoltage radiation than it is following 200,000-volt treatment.

The follow up period on the cases which we have treated by supervoltage x ray is too short for us to draw conclusions as to end results.

It should be kept in mind that radiation therapy is not a strictly technical procedure, and that success or failure depends on the training, judgment and ability of the radiologist more than on the apparatus at his disposal.

DR. O BRIEN (closing) I have very little to add, gentlemen. The purpose of my paper was to try to prevent an unreasoned stampede to supervoltage therapy. Lest you think that I have an ax to grind, I may say I have installed and am operating a 400,000-volt machine in my private office. I am as anxious as anyone to have supervoltage x rays utilized in an attempt at the cure of cancer, but I want to do it with an open mind.

The statements which Dr. Dresser made as to greater intensity and depth dose when using 1,000,000 volts nobody disputes from the physical standpoint, but their clinical

application is another matter. Dr. Dresser failed to mention the disadvantages of 1,000,000-volt therapy, and this is the nub of the matter, for they are many. Something more than magnitude of potential is essential in the treating of tumors. While the relative depth dose at 1,000,000 volts is greater than that at 200,000, the total dose that one may deliver to a tumor may under certain conditions be greater with the latter. In thin patients very little is gained by using supervoltage. In heavy ones, if one uses small portals and avoids crossfire and overlapping on the opposite skin, supervoltage can be used to advantage. In crossfire technic the large doses on the surface of exit to which I have referred in my paper limit the practical value of the large depth doses.

As for the reputed greater skin tolerance, opinion is crystallizing that if one uses equal intensities and time spacing the skin reaction is about the same. Regarding less roentgen sickness, we have had less since we started putting our tubes in oil, enclosing the high tension leads and properly ventilating our treatment rooms. I know of no evidence that a 1,000,000-volt irradiation is more kindly to the intestinal mucosa than is one of 200,000 volts.

That the depth dose when using 1,000,000 volts is practically independent of the size of the portal employed is a physical fact of interest. But the fact that back scatter makes up a large part of the depth dose when using 200,000 volts does not constitute a valid argument in favor of one or against the other. If the skin effect is in reality less when supervoltage x rays are used, this may be due to the wave lengths, which are of the order of gamma rays—although biologists working with seedlings and tissue cultures have not demonstrated any specificity.

Million volt x ray therapy is new only to Boston. Supervoltage therapy may prove to be a most potent force in dealing with cancer, but those who have employed it elsewhere for almost a decade are most guarded in evaluating it.

## PHYSICAL THERAPY IN ARTHRITIS\*

FRANK H KRUSEN, MD †

ROCHESTER, MINNESOTA

THERE are three physical measures which may be used in the treatment of arthritis heat, massage, manipulation and splintage, and exercise, postural training and rest. Unfortunately, the use of physical measures in the treatment of arthritis has been to a great extent neglected by the medical profession. There is a pronounced need for the more extensive application of such means in the home.

That there can be no doubt of the value of these methods is attested by leading experts in this field. Fox and Van Breemen<sup>1</sup> have said, "We rely to a great extent on physical medicine." Copeman<sup>2</sup> has said, "One of the most important advances of this century is the discovery that the human body can be influenced as much from the outside by physical methods as from the inside by medicinal methods." Hench<sup>3</sup> has stated that in the treatment of arthritis "physical therapy remains the most potent weapon at hand," and finally, Pemberton and Osgood<sup>4</sup> have asserted, "Any discussion of arthritis which does not at the same time develop, at length, the important field of physical therapy would be a medical incongruity."

## REST

For all patients who have chronic infectious (rheumatoid) arthritis, rest should be prescribed in definite amounts, from a basic minimum of ten hours in bed at night and one hour of rest each morning and afternoon. A few patients may require slightly less than this amount of rest, whereas others may require somewhat more. During the acute stage of the disease rest is of cardinal importance. After this stage has been passed, the patient should be warned against traumatizing the joint by weight bearing and instructed to avoid irritation from repeated aimless movements of the joints involved. He should never wiggle the affected joints. Instead he should carry through the full range of motion in each direction once a day. This attempt should be slow and rhythmic. Sir Robert Jones<sup>5</sup> has said, "No adhesions can occur in twenty four hours which cannot easily be overcome."

The patient who has chronic infectious (rheumatoid) arthritis should avoid general fatigue

rather than remain at absolute rest. He should avoid hurry and worry, and at the same time should take enough non-fatiguing general exercises to improve metabolism and posture. He should also take sufficient local exercise to maintain proper mobilization and alignment of the joints.

## THERMAL AGENTS

Insufficient attention has been paid to the use of certain simple physical measures for systemic heating in the treatment of arthritis. Hot tub baths taken by the patient in his own bath tub may be of considerable value in increasing peripheral circulation and the general metabolism. The temperature of the water may range between 98 and 105°F (36.6 and 40.6°C) and the duration of the treatment may be between ten and forty-five minutes. At the beginning, the lower temperatures and shorter periods of time should be used. Asthenic and emaciated patients should be treated with caution. The full wet pack may also be used to advantage in the treatment of arthritis in the home. Furthermore, with a little ingenuity the physician may have constructed a simple cabinet or steam bath for applying heat to the surface of the entire body.<sup>6</sup>

Local heating of one or more involved joints may best be done with a simple home-made baker or a so-called clamp lamp, which likewise is inexpensive. The baker may be constructed by any tinsmith at the cost of a few dollars. It consists of a framework of strap iron supporting a curved piece of polished sheet tin beneath which four sixty-watt bulbs are placed in double sockets. Specifications for the construction of this apparatus may be obtained by writing to the secretary of the Council on Physical Therapy of the American Medical Association. The clamp lamp consists of a cup shaped "photo-flash" reflector attached by a ball and socket joint to a small rubber clamp, which may be fastened to the back of a chair or the side of a bed. In the reflector is placed a two-hundred and fifty-watt Mazda CX bulb. I have described this lamp in detail elsewhere.<sup>7</sup>

The use of these luminous heaters is to be preferred to the use of the common electric heating pad. The latter often become too hot for proper local treatment, and we have discouraged their use because they are liable to burn the skin. Hench<sup>8</sup> has shown that the average low tem-

Boston, June 2, 1933.

†Head of Section on Physical Therapy, the Mayo Clinic.

perature of an electric heating pad is approximately 107.6°F (42°C), the medium temperature 181.4°F (82°C) and the high temperature 244.4°F (118°C). These temperatures are entirely too high for the local treatment of the average arthritic joint.

Physicians are occasionally faced with the problem of prescribing a method of local heating for patients who do not have electricity in their homes. We have experimented with special bakery heaters heated by means of "canned heat", however, these are comparatively expensive to operate and can be applied satisfactorily only to the extremities. Currently, therefore, we recommend the local application of ordinary paraffin.<sup>9</sup> Practically every patient has in his home a kitchen stove and a double boiler, and can obtain from the nearest grocery store several pounds of ordinary paraffin such as is used for sealing preserve jars. The patient is instructed to fill the outer container of the double boiler with water and place the paraffin in the inner container. The paraffin is then heated to the melting point and is allowed to cool until a thin film has formed on the surface. At this time, when the paraffin is at its low melting point, the temperature will be just tolerable to the human skin. The paraffin may then be painted over the involved joint with an ordinary paint brush or a smooth stick of wood wrapped in gauze or linen. About a dozen coats are applied successively and the paraffin is allowed to remain on the area to be treated for thirty minutes or an hour. It should never be applied over a hairy skin without preliminary oiling or shaving. Rarely, a patient's skin is sensitive to paraffin and a slight rash is produced.

On wrists, ankles or knees it is sometimes advisable to use a dressing of paraffin and gauze. The technic is simple. First a layer of paraffin is painted around the joint, next a few turns of gauze are applied to cover the first layer of paraffin. Successive layers of gauze and paraffin are applied until a thick, firm dressing surrounds the joint. Such a dressing will retain its heat for approximately one hour, and the dressing may be left on for twenty-four hours to provide a firm support for the joint. It should then be removed in order that massage and exercise may be administered prior to the application of a similar dressing.

In some cases of atrophic arthritis, applications of cold may be indicated. The so-called "Winteritz bath" has been used extensively in Europe. It consists of immersing the patient in a tub bath the temperature of which is a few degrees below that of the blood, and applying brisk, rapid friction to the surface of the skin during immersion. This seems to have a tonic effect and enables pa-

tients who are susceptible to cold to become tolerant to it gradually.

Frequently, alternate local applications of heat and cold are of benefit. For years specialists in arthritis have used contrast baths, particularly in the treatment of hypertrophic arthritis of the hands and feet. Some recent studies<sup>10</sup> indicate that they should be applied for longer periods than was formerly the custom. It now seems likely that periods of six minutes of heat and four of cold or seven minutes of heat and three of cold are most satisfactory for the average patient with chronic infectious (rheumatoid) or senescent arthritis. The hot water is kept at a temperature of approximately 113°F (45°C) and the cold water at about 45°F (7.2°C), and periods of thirty or forty minutes are devoted to each session.

#### HELIO THERAPY

The use of ultraviolet irradiation is of occasional value in chronic infectious (rheumatoid) arthritis, particularly if there is severe asthenia and secondary anemia. If it is possible to apply direct sunlight to the entire body, Rollier's method of gradual insolation is usually most satisfactory.<sup>11</sup> If an artificial source must be used in the home, the so-called S-1 lamp is as satisfactory as any. At a distance of two feet it produces about the same quality and quantity of ultraviolet radiation as does June sunlight at noontime.

#### MASSAGE

Massage should not be used if there is acute pain on movement of the involved joint or if there is a rise of temperature in the region of the joint. As a rule, in cases of arthritis massage of the joints is avoided, although extremely light effleurage (or stroking) may occasionally be used for reflex relief of pain. As the condition improves, one may gradually increase the intensity of stroking and kneading of the muscles around the joint in an attempt to improve the circulation and tone of the muscle. We have found that it is possible for a skilled technician to instruct a member of the family in a few simple massage strokes which may be used to augment professional treatment.<sup>8</sup>

#### MANIPULATION

Vigorous manipulation applied only when the patient has been anesthetized may be a powerful weapon in the improvement of function in cases of quiescent, traumatic or infectious (rheumatoid) arthritis. Such manipulation is strictly an orthopedic procedure, and requires a great deal of experience for its proper application. Henderson<sup>12</sup> has stated that manipulation of this sort requires more experience than any other orthopedic procedure. It is therefore apparent that such manipulation should always be performed by skilled

hands The joints which respond particularly well to such manipulation are those of the shoulder, hip and knee It should always be remembered, however, that it is useless to straighten a knee unless the hip, ankle and foot of the same extremity are capable of functioning The joints which respond in most cases very poorly to manipulation are the elbow joint, wrist joint and joints of the fingers

It should always be remembered that it is often possible to manipulate arthritic joints gently without anesthesia by means of a procedure which may be termed "active assistive exercise" The patient makes an active effort to move the joint as nearly as possible through its full range of motion and is assisted by the operator in carrying the movement a little beyond this range Applied slowly and skillfully once or twice a day just after the part has been heated and massaged, such a procedure frequently produces a gradual but great increase in range of motion This active assistive exercise should always be attempted for at least three weeks before more severe measures under anesthesia are attempted At no time should the operator jerk or pull the joint violently He should apply pressure slowly, gradually and just short of producing severe pain If there is still increased pain in the joint twenty-four hours later, it will be known that the measure was performed too severely, and that it should be discontinued for one or two days and then applied less strenuously than before This same program of active assistive movement should always be started within twenty-four hours after a severe manipulation under anesthesia, in order that the mobility of the joint may be maintained It is far better to give a strong sedative or narcotic and to exercise the joint early than it is to allow it to remain at rest until adhesions have formed

It has been shown recently<sup>13 14</sup> that traction and rotation of the cervical portion of the spine may relieve radiculitis secondary to hypertrophic arthritis of the cervical spine and involving the shoulder girdle, arm or precordium This type of segmental neuritis is probably much more frequent than is generally recognized, and the application of heat, massage and traction by means of the Sayre head sling, with mild, forced rotation of the neck during traction, often seems to give considerable relief

#### SPLINTS

In considering every case of chronic infectious (rheumatoid) arthritis, the physician should remember that, above all, every effort should be made to prevent deformities Once deformities develop, it may take years to correct them The

chief deformities likely to arise in this type of arthritis are adduction of the shoulders, thoracic kyphosis with fixation, flexion of the elbows, wrists or knees, loss of abduction of the hips and foot drop The proper application of splints will prevent such deformities

The patient must always use a bed which does not sag At least twice a day he should discard all pillows and fully extend all his joints for a half hour Once deformities have developed, wedged casts or traction may be required to overcome contractures It is particularly important to remember that such patients should avoid the constant use of pillows under the knees, because this is one of the most frequent causes of flexion contractures of the knees

#### SHOES AND SUPPORTS

The physician should never permit the patient to wear shapeless bedroom slippers continually Patients are frequently of the erroneous belief that such slippers are more comfortable than are shoes As a matter of fact, they merely exaggerate deformities and are not nearly so comfortable as well-fitting orthopedic shoes equipped with a metatarsal bar on the sole just posterior to the transverse arch of the foot, heel pads or wedges, and a soft felt pad to support the longitudinal arch of the foot Rigid metal arch supports are not to be favored, for they are not well tolerated by the patient who has arthritis, and they tend to produce pressure atrophy of the plantar muscles<sup>15</sup> Elastic supports for the knee or ankle or properly applied ace bandages are frequently of value when applied to the knee or ankle, but are rarely of use for other joints Sacroiliac belts occasionally afford considerable comfort

#### EXERCISE

Exercise is always necessary in the treatment of chronic infectious (rheumatoid) arthritis In Nature's warning, in the form of severe pain and acute cases in which motion is started prematurely, spasm, will usually prevent continuation of such motion As soon as the patient starts wary voluntary motion, this is the signal for the inauguration of gentle passive motion by the operator Exercises should be graduated slowly from passive motion to active assistive motion and, finally, to fully active motion Knees should be exercised at first with the patient in the prone position in order to avoid the strain of weight bearing The knees should always be straightened as much as possible before walking is attempted Exercises should be slow and rhythmic and through the fullest range of motion that is painless One should always avoid jerking, wiggling and pump-

perature of an electric heating pad is approximately 107.6°F (42°C), the medium temperature 181.4°F (82°C) and the high temperature 244.4°F (118°C). These temperatures are entirely too high for the local treatment of the average arthritic joint.

Physicians are occasionally faced with the problem of prescribing a method of local heating for patients who do not have electricity in their homes. We have experimented with special bakers heated by means of "canned heat", however, these are comparatively expensive to operate and can be applied satisfactorily only to the extremities. Currently, therefore, we recommend the local application of ordinary paraffin.<sup>9</sup> Practically every patient has in his home a kitchen stove and a double boiler, and can obtain from the nearest grocery store several pounds of ordinary paraffin such as is used for sealing preserve jars. The patient is instructed to fill the outer container of the double boiler with water and place the paraffin in the inner container. The paraffin is then heated to the melting point and is allowed to cool until a thin film has formed on the surface. At this time, when the paraffin is at its low melting point, the temperature will be just tolerable to the human skin. The paraffin may then be painted over the involved joint with an ordinary paint brush or a smooth stick of wood wrapped in gauze or linen. About a dozen coats are applied successively and the paraffin is allowed to remain on the area to be treated for thirty minutes or an hour. It should never be applied over a hairy skin without preliminary oiling or shaving. Rarely, a patient's skin is sensitive to paraffin and a slight rash is produced.

On wrists, ankles or knees it is sometimes advisable to use a dressing of paraffin and gauze. The technic is simple. First a layer of paraffin is painted around the joint, next a few turns of gauze are applied to cover the first layer of paraffin. Successive layers of gauze and paraffin are applied until a thick, firm dressing surrounds the joint. Such a dressing will retain its heat for approximately one hour, and the dressing may be left on for twenty-four hours to provide a firm support for the joint. It should then be removed in order that massage and exercise may be administered prior to the application of a similar dressing.

In some cases of atrophic arthritis, applications of cold may be indicated. The so-called "Winter-nitz bath" has been used extensively in Europe. It consists of immersing the patient in a tub bath the temperature of which is a few degrees below that of the blood, and applying brisk, rapid friction to the surface of the skin during immersion. This seems to have a tonic effect and enables pa-

tients who are susceptible to cold to become tolerant to it gradually.

Frequently, alternate local applications of heat and cold are of benefit. For years specialists in arthritis have used contrast baths, particularly in the treatment of hypertrophic arthritis of the hands and feet. Some recent studies<sup>10</sup> indicate that they should be applied for longer periods than was formerly the custom. It now seems likely that periods of six minutes of heat and four of cold or seven minutes of heat and three of cold are most satisfactory for the average patient with chronic infectious (rheumatoid) or senescent arthritis. The hot water is kept at a temperature of approximately 113°F (45°C) and the cold water at about 45°F (7.2°C), and periods of thirty or forty minutes are devoted to each session.

#### HELIOOTHERAPY

The use of ultraviolet irradiation is of occasional value in chronic infectious (rheumatoid) arthritis, particularly if there is severe asthenia and secondary anemia. If it is possible to apply direct sunlight to the entire body, Rollier's method of gradual insolation is usually most satisfactory.<sup>11</sup> If an artificial source must be used in the home, the so-called S-1 lamp is as satisfactory as any. At a distance of two feet it produces about the same quality and quantity of ultraviolet radiation as does June sunlight at noontime.

#### MASSAGE

Massage should not be used if there is acute pain on movement of the involved joint or if there is a rise of temperature in the region of the joint. As a rule, in cases of arthritis massage of the joints is avoided, although extremely light effleurage (or stroking) may occasionally be used for reflex relief of pain. As the condition improves, one may gradually increase the intensity of stroking and kneading of the muscles around the joint in an attempt to improve the circulation and tone of the muscle. We have found that it is possible for a skilled technician to instruct a member of the family in a few simple massage strokes which may be used to augment professional treatment.<sup>12</sup>

#### MANIPULATION

Vigorous manipulation applied only when the patient has been anesthetized may be a powerful weapon in the improvement of function in cases of quiescent, traumatic or infectious (rheumatoid) arthritis. Such manipulation is strictly an orthopedic procedure, and requires a great deal of experience for its proper application. Henderson<sup>13</sup> has stated that manipulation of this sort requires more experience than any other orthopedic procedure. It is therefore apparent that such manipulation should always be performed by skilled

more attention to this condition and to the use of firm massage in its treatment<sup>19</sup>

#### FEVER THERAPY

The results of treatment of chronic infectious (rheumatoid) arthritis with prolonged fever therapy at the Mayo Clinic have not been particularly encouraging. Approximately 10 per cent of patients showed much improvement, and 20 per cent moderate improvement, the remaining 70 per cent showed little or no improvement<sup>20</sup>. On the other hand, daily fever therapy of short duration (thirty minutes), administered either in a tub or a fever cabinet, may be a valuable adjunct in routine physical treatment. In practically all cases, such short periods of fever therapy are followed by massage and exercise of the involved joints.

In cases of gonorrheal arthritis, prolonged fever therapy is of the utmost value, although, since the advent of sulfanilamide, fever therapy is not so frequently indicated as formerly. Our recent studies<sup>21</sup> indicated, however, that about 10 per cent of the patients who had gonorrhea failed to respond to sulfanilamide alone. In these cases we now recommend combined sulfanilamide and fever therapy. In 25 cases of gonorrhea in which a response to sulfanilamide failed to occur, a prompt response was obtained by this combination.

#### CONCLUSIONS

Physical measures are of very great value in the management of both chronic infectious (rheumatoid) and hypertrophic arthritis. Many of these may be used to great advantage in the home. It would be of particular advantage for the general practitioner to apply such procedures extensively.

#### DISCUSSION

DR. FRANK OBER, Boston. I think we are very fortunate in having a man like Dr. Krusen here. He is one of the real pioneer preachers of good physical therapy. He is a member of the Council of Physical Therapy of the American Medical Association, and his words and advice are always well considered and timely.

In Massachusetts a few years ago the Governor appointed a commission to study the health laws of the state and their rejuvenation. Dr. Osgood was chairman of the section on adult hygiene, and Drs. George Minot, Walter Bauer, Robert Greenough, Elliott Joslin, William Robey and I were members of the section to study cancer, diabetes, circulatory diseases and arthritis. After we went into the situation very thoroughly and carefully, we came to the conclusion that the first thing required in the treatment of these chronic diseases, especially arthritis, was brains. We thought that if we had a large metropolitan hospital, it would probably be put in the center of population of Massachusetts and would be nothing but an almshouse. The section recommended to the legislature that a few beds be set aside in a hospital for the care of arthritic patients. Dr. Chadwick, the commissioner of health, sat in on all meetings and heard all the arguments pro and con. Finally, a year ago the legislature raised a sum of money, which was set aside for the care of patients with chronic arthritis, and these funds are being spent at the Massachusetts General Hospital, where Dr. Bauer has been conducting research work in arthritis for eight or ten years.

The next step will probably be to set up some form of home treatment for the arthritic patient. This is very vital, because there are too many arthritic cases in Massachusetts for all to be housed in institutions. There is not money enough to build more institutions, and we have not enough personnel to carry them on if the money were available. We certainly have not enough educated personnel to manage more than one or two, so it seems unwise to advocate large institutions for the handling of arthritic patients. The treatment should therefore be carried on at home. Furthermore, the patient is a little happier there. We do need a place where the patient can go through a sort of clearing station for study and care of all the aspects of his joint condition. The family and the family physician should be brought into the picture because they will be responsible for the care of the patient.

The care of the arthritic patient comes under three heads. First, medical there is no point in taking care of an arthritic joint until one finds out what is the matter with the patient. Secondly, orthopedic treatment the orthopedic surgeon has come to acquire a special knowledge of joints and of the manipulation of painful ones, necessary because so many can be injured by poor massage. Deep massage and passive manipulations, by ignorant persons, have ruined many a good joint that might otherwise have been saved. Finally, there is the application of physical therapy measures which have been pre-

handle movements. One slow daily movement through the fullest, possible range of motion is preferable to many minor ones through a partial range of motion.

#### POSTURAL EXERCISES

Properly applied postural exercises rebalance the body as a whole so that there is better alignment of the joints and avoidance of strain. It has also been suggested<sup>16</sup> that postural exercises tend to promote normal visceral function. It has been pointed out<sup>17</sup> that hypertrophic arthritis always involves the points of greatest chronic strain in the spine, neck, fingers, knees and hips. With the exception of the fingers, all these joints are involved in bearing weight, and it seems logical to assume that postural exercises tend to lessen the strain on these joints by improving alignment. The patient who has arthritis and faulty posture should always be taught the following five cardinal exercises: walking with the feet pointed straight ahead and with the weight evenly distributed, rolling the hips under (contracting the gluteal muscles downward and the abdominal muscles upward, thus rotating the pelvis into a more level position), raising the chest, lifting the back part of the head toward the ceiling (thus straightening the dorsal and cervical spine), and walking, standing and sitting as erectly as possible.

Special attention should be directed toward exercises for the feet. Routine exercises for correction of pronated feet may often be in order.

#### EXERCISES UNDER WATER

Exercises performed under water may be of much value in the treatment of extensive chronic infectious (rheumatoid) arthritis. Some of these exercises may be done in the patient's own bath tub, or occasionally a Hubbard tank may be constructed.\* The temperature of the water should vary between 98 and 105°F (36.6 and 40.6°C), and massage and exercises may be given under water during the period of maximal hyperthermia. If the palms of the operator are slightly oiled, he can massage under water without difficulty. It is possible by means of such baths to produce mild febrile reactions not unlike those produced by administration of typhoid vaccine. The bodily temperature may readily be raised within thirty minutes to 101°F (38.3°C). Movements can be carried through a greater arc with less pain under water, and because of the buoyancy of water, weak muscles are capable of a greater amount of work. Most observers agree that for a patient

who has advanced infectious (rheumatoid) arthritis, the best way to start walking is in a pool.

#### OCCUPATIONAL THERAPY

Occupational therapy is extremely important in the rehabilitation of the patient with arthritis. For the knee, hip or ankle one may use a velocipede jigsaw or a stationary bicycle. For the ankle, one may utilize a foot pedal scroll saw or an ordinary sewing machine. For exercising stiff fingers and wrists, modeling with clay or hammering and planing is of value. For the shoulder, elbow and upper part of the back suitable exercises may be provided by having the patient do basket making or loom-weaving, with the materials placed high enough to cause him to increase the upward range of shoulder motion as he works. A skilled occupational therapist can teach the patient many curative occupational procedures, most of which may be carried out at home.

#### HYDROTHERAPY

As previously mentioned, hot baths may raise the temperature of the patient above 101°F (38.3°C), and it has been shown by Currence<sup>18</sup> that they also increase the number of leukocytes, the circulation in the capillaries of the nail beds and the metabolic rate. The whirlpool bath may frequently be used to advantage in the treatment of arthritis involving the joints of the extremities. The part to be treated is placed in a bath of whirling aerated water at a temperature of 110°F (43.3°C), usually for thirty to forty-five minutes. Such a bath produces great dilatation of the peripheral capillaries, a soothing effect on the peripheral nerve endings and relaxation of the muscles. A simple whirlpool bath can be constructed for a few dollars.†

#### FIBROSITIS

This condition, which is described at great length in the Continental literature, is often unrecognized in this country. It consists of chronic inflammation of white fibrous tissue, and is particularly characterized by the formation of small palpable nodules in the subcutaneous tissue or muscles. It is of special interest to the physical therapist, because it has been claimed repeatedly that a certain type of very firm massage is of great value in treatment. It has been stated repeatedly by British authors that very firm local massage will "break up" many of the nodules, with subsequent relief from pain and muscle spasm. It would seem that American physicians should pay

\* Specifications may be obtained from the Secretary of the Council on Physical Therapy of the American Medical Association, 535 North Dearborn Street, Chicago, Illinois.

† Specifications may be obtained from the Secretary of the Council on Physical Therapy of the American Medical Association, 535 North Dearborn Street, Chicago, Illinois.

more attention to this condition and to the use of firm massage in its treatment.<sup>19</sup>

#### FEVER THERAPY

The results of treatment of chronic infectious (rheumatoid) arthritis with prolonged fever therapy at the Mayo Clinic have not been particularly encouraging. Approximately 10 per cent of patients showed much improvement, and 20 per cent moderate improvement, the remaining 70 per cent showed little or no improvement.<sup>20</sup> On the other hand, daily fever therapy of short duration (thirty minutes), administered either in a tub or a fever cabinet, may be a valuable adjunct in routine physical treatment. In practically all cases, such short periods of fever therapy are followed by massage and exercise of the involved joints.

In cases of gonorrheal arthritis, prolonged fever therapy is of the utmost value, although, since the advent of sulfanilamide, fever therapy is not so frequently indicated as formerly. Our recent studies<sup>21</sup> indicated, however, that about 10 per cent of the patients who had gonorrhea failed to respond to sulfanilamide alone. In these cases we now recommend combined sulfanilamide and fever therapy. In 25 cases of gonorrhea in which a response to sulfanilamide failed to occur, a prompt response was obtained by this combination.

#### CONCLUSIONS

Physical measures are of very great value in the management of both chronic infectious (rheumatoid) and hypertrophic arthritis. Many of these may be used to great advantage in the home. It would be of particular advantage for the general practitioner to apply such procedures extensively.

#### DISCUSSION

DR. FRANK OBER, Boston. I think we are very fortunate in having a man like Dr. Krusen here. He is one of the real pioneer preachers of good physical therapy. He is a member of the Council of Physical Therapy of the American Medical Association, and his words and advice are always well considered and timely.

In Massachusetts a few years ago the Governor appointed a commission to study the health laws of the state and their rejuvenation. Dr. Osgood was chairman of the section on adult hygiene, and Drs. George Minot, Walter Bauer, Robert Greenough, Elliott Joslin, William Robey, and I were members of the section to study cancer, diabetes, circulatory diseases and arthritis. After we went into the situation very thoroughly and carefully, we came to the conclusion that the first thing required in the treatment of these chronic diseases, especially arthritis, was brains. We thought that if we had a large metropolitan hospital, it would probably be put in the center of population of Massachusetts and would be nothing but an almshouse. The section recommended to the legislature that a few beds be set aside in a hospital for the care of arthritic patients. Dr. Chadwick, the commissioner of health, sat in on all meetings and heard all the arguments pro and con. Finally, a year ago the legislature raised a sum of money, which was set aside for the care of patients with chronic arthritis, and these funds are being spent at the Massachusetts General Hospital, where Dr. Bauer has been conducting research work in arthritis for eight or ten years.

The next step will probably be to set up some form of home treatment for the arthritic patient. This is very vital, because there are too many arthritic cases in Massachusetts for all to be housed in institutions. There is not money enough to build more institutions, and we have not enough personnel to carry them on if the money were available. We certainly have not enough educated personnel to manage more than one or two, so it seems unwise to advocate large institutions for the handling of arthritic patients. The treatment should therefore be carried on at home. Furthermore, the patient is a little happier there. We do need a place where the patient can go through a sort of clearing station for study and care of all the aspects of his joint condition. The family and the family physician should be brought into the picture because they will be responsible for the care of the patient.

The care of the arthritic patient comes under three heads. First, medical: there is no point in taking care of an arthritic joint until one finds out what is the matter with the patient. Secondly, orthopedic: treatment the orthopedic surgeon has come to acquire a special knowledge of joints and of the manipulation of painful ones, necessary because so many can be injured by poor massage. Deep massage and passive manipulations, by ignorant persons, have ruined many a good joint that might otherwise have been saved. Finally, there is the application of physical therapy measures which have been pre-

scribed by the doctor and the orthopedic surgeon at the proper time.

As to heat, it is important for the arthritic patient to keep warm if he is a bed patient. If he gets chilled at night he is sure to have an uncomfortable day. There are occasional patients who cannot stand heat in any form, and it should not be forced upon them. I have a patient who keeps her room temperature at 60 degrees all the time. If it rises to 65 or 68 degrees she is always uncomfortable. Heat may be overdone in the care of arthritis in general. In reference to massage, it is impossible to massage arthritis out of joints, and I do not believe that we can massage fibrous masses out of muscles, especially out of tendons, where they are prone to occur.

Rest, of course, which Dr Krusen spoke of at the end, is one of the most important factors in the management of this disease. Rest of the patient, if ill, and rest of the joint—two considerations for rest. One needs to know whether the joint is the so-called hypertrophic or degenerative type, or the so-called atrophic or proliferative type. The first type will not ankylose. It will lose motion if enough bone is formed by overexercise to irritate the joint. In the proliferative type, which is prone to ankylosis, we must have movement. The movement should not be through the whole range of the normal joint motion, but within the range of discomfort. Thomas splints should be used with the patient in bed, with an overhead arrangement of pulleys, splints jointed at the knees and ankles, elbows and shoulders, so that they can be run by the patient. They can be built at home with little difficulty with a frame over the bed, a gaspipe apparatus or some posts hung on the corners of the bed.

When patients go through these motions, they should be taught how to use their muscles actively. Passive motion alone will irritate a joint, because passive motion tears the delicate joint membrane, and every time the joint membrane is torn pain and muscle spasm occur—an effort on the part of nature to splint the joint. Small hemorrhages take place in the joint, and there is an increase in the ankylosing type of tissue. The early motion should be active plus passive. A patient who has an acute arthritic joint—a knee, for instance—cannot stand very much motion. The first thing we have to combat is pain, which we can do with medication of some sort, plus a splint. The patient is then taught how to contract rhythmically the muscles that control the joint. That is, the first effort to improve the physiology of a knee joint is to teach the patient how to tighten and relax his quadriceps muscle. The quadriceps muscle in an inflamed knee is always atrophied. It is impossible for this patient to walk on an inflamed knee which has not muscle power enough to support the body weight on his leg when he is erect. The exercise should be done every hour by short rhythmic contractions and relaxations, not hard enough to produce pain. These exercises improve the tone of the skin, the circulation and the muscles and combat bone atrophy. When we combat bone atrophy we are on the road to combating atrophy of the cartilage, which is one of the factors in the production of ankylosis of these arthritic joints. As soon as these patients have enough muscle to hold the knees straight against gravity we can begin active exercises.

It is a bad practice to splint a joint indefinitely. If there is an ankylosing type of arthritis of the knee, and the knee is kept in a plaster cast, bone atrophy increases and as a result the joint collapses. Ankylosis then occurs. The splints must be removed once or twice a day for exercise in order to stimulate the joint function. The mere setting of the muscle will do so.

It is unfortunate that many ready made shoes do not fit properly. There are over four hundred million pairs of shoes produced in the United States every year, and they do not fit anybody accurately. We might as well go out and buy window glass for spectacles as to buy shoes the way we do. It is for this reason that a shoe has to be rebuilt by the surgeon. If we have a pronated foot that is kept pronated by spasm of the peroneal muscles, we cannot apply the sort of shoe that Dr Krusen advocates because it works against the spasm of the muscle. One has to apply a shoe that allows the foot to be pronated until the spasm has gone from the muscles or until manipulation has relieved the tension of the muscle.

No force should ever be used on an ankylosed type of arthritic joint, because it will do nothing but irritate the joint.

One of the symptoms of arthritis of the neck is pain at the root of the neck. In addition, there may be pain going down the arm along one or more or all the nerves of the brachial plexus. The Sayre head sling, which most orthopedic surgeons have used for years, is a very simple apparatus for use in this contraction. A good brace shop will make up a leather sling for very little money. One needs a double and a single block of the awning type, awning line and an awning screw and the header of a closet doorway. The patient sits in a chair and is instructed to pull on the rope and stretch his neck very slowly and very gradually. He should not pull more than eight or ten times twice a day. Some of these patients are inclined to pull themselves off the chair and wonder why they have so much pain in their necks.

Often associated with this type of arthritis we have chronic headache and sometimes chronic sore throat. Chronic headache at the base of the skull is caused by spasm of the trapezius muscle. It is sometimes referred all the way over the skull to the eyebrow. In a great many cases where no other cause for the headache can be found, it may be discovered that severe arthritis of the cervical spine is the producing factor. The use of the Sayre sling is of great help in these cases.

When these patients are able to stand they usually have a bad posture because they have been ill for a long time. They must have corrective exercises for their postural difficulties.

The Marie Strumpell type of arthritis, that is, the ankylosing type, which usually affects the spine oftener in men than women (about 9 men to 1 woman), is a very disabling condition. These patients usually go around bent over at the waist. Once in a while one sees a patient walking about the streets of Boston with his hands almost on the sidewalk. Whenever it is suspected that a patient has arthritis of the spine, the chest should be measured, since one of the early symptoms in this type of arthritis is diminution of the respiratory excursion. It may be as little as a quarter of an inch. These patients must have deep breathing exercises, preferably lying on the floor, on a hard surface. They need something to increase the chest expansion, this helps a little bit in diminishing their deformity. Occasionally patients with chronic arthritis get flexion contracture of the hip, the muscles becoming shortened. One patient I saw not long ago, a man about six feet tall, had developed a 35-degree flexion contracture of the hips, being a very intelligent man but very much depressed, he said, 'My one difficulty is that I cannot look my fellow man in the face. If I could be sure that I could look him straight in the eye once in a while, I should feel much better from the psychological point of view.' His flexion deformity was relieved by dividing his contracted

hip fasciae. Getting rid of 35 degrees of hip flexion contraction allowed him to stand up straight and he began to improve in his general condition within three or four weeks.

We have found underwater exercises in the early stages of arthritis in children very valuable. These children are taught to do their exercises under water.

A good many patients claim that after a good night's sleep they do not feel so well the next morning. They conclude from this that they are much worse. Now, patients who are uncomfortable through the night are usually better in the morning because they have had physical therapy throughout the night. In other words, every time they have turned over in bed they have been awakened and have had to move their joints in various positions. Thus, a patient who is awake at intervals during the night is usually better in the day. In other words, their joints do not get a chance to stiffen up as they do when they sleep a long time in one position.

Sometimes one may think that a patient's joints are worse. The patient may complain that he feels very much more uncomfortable than he did a month before. He thinks he has had a new attack or an increase in the arthritis. If there is a sudden disappearance of fluid and the membranes in that joint come together, the two surfaces rub against each other and the patient has more pain. This does not mean that he is worse. These patients usually take two or three days to recover under rest and then go on again for a month or two. The swelling of the joint membrane gradually decreases, and then there is another attack of pain. One finds that there is a little less thickening and a little smaller joint, but there is a little more rubbing and grating than before. It does not mean that there is a recurrence or increase in the arthritis.

Another word about heat. Heat never cured arthritis. Dr. Krusen knows as well as I do that there is a great effort being made in this country to sell every doctor a short wave diathermy machine. The propaganda for heat therapy and short wave diathermy machines is going on at a great pace. I do not know how many different machines there are—probably over a hundred. You can buy them from \$145 to \$4500. It looks to me as if everybody would have a short wave diathermy machine to treat all sorts of diseases. One cannot treat arthritis with heat alone. There must be a variety of treatment—a finding out of what is the matter with the patient and getting rid of it by the medical man, splinting and care of joints by an orthopedic surgeon, and the use of heat, massage and exercise by the physical therapist.

DR. GEORGE R. MINOT, Boston. Dr. Krusen has given us an excellent exposition of a most important form of treatment to be used in arthritis.

In the treatment of this disease, there are certain principles to keep in mind to improve all functions of the body and to modify or to remove any basic causes. The difficulty very often is that we do not know what the basic causes are. We must make adjustments to lessen the burden of the handicapped organism. It is important to know intimately one's patient. Time must be spent obtaining a detailed history and becoming sufficiently acquainted with the individual to understand his reaction to his fellow men, to his home, his environment, his country, to all those problems of life often spoken of as social aspects of medical cases. If one thoroughly understands the patient as a human being, one will be able to aid him.

As has been mentioned by Dr. Krusen and Dr. Ober, rest is undoubtedly of the utmost importance in treatment. Physical therapy is going to help us gain that rest. You

remember Dr. Krusen explained that following the use of packs the individual is relaxed and goes to sleep. Anything we can do to gain rest, physical or mental, is going to be of advantage to the patient. Rest means more than going to bed. One who has gone to bed may become very restless, have tense muscles, be worried, be overactive mentally, be unduly anxious. Merely saying that he should take a rest or go to bed for an hour will accomplish nothing. Each patient presents a separate problem. A precise program of rest, adjusted to the given case, can be prescribed intelligently only after one thoroughly understands the patient, including his reactions to other individuals and his environment. The goal is to obtain habitual relaxation and tranquility.

An acquaintance with Jacobson's studies on progressive relaxation can be serviceable in aiding these patients. Relaxation does not mean simply diversion. Indeed, rest may mean extraordinarily different things to different people. I recall a woman with rheumatoid arthritis who was advised to rest for an hour in the morning, an hour in the afternoon, with clothes off, in bed. She became progressively worse. At the end of about two months it was realized that those in charge of her case did not know exactly what she did when she rested. On inspection of the home and finding out the exact circumstances of her rests, it was learned that they consisted of lying on the bed with the telephone beside her, which she answered whenever it rang and sent messages. Furthermore, she kept pencil and paper in hand and constantly made notes regarding many sorts of matters to be attended to. She was lying down, that meant rest to her.

A policeman was advised to rest, nothing more was said to him about this matter. Rest to him meant diversion. He thus took his family in his automobile from Boston to the Pacific Coast in about twelve days.

One must prescribe rest. To some individuals that may mean diversion, to others to become a complete sloth. Just as rest may mean different things to different people, we must realize that the word fatigue, as L. J. Henderson has pointed out, can be applied to many different conditions. The word fatigue is used, for example, for feelings arising from utterly different physiologic processes, for example from lack of oxygen, from low blood sugar, from that condition associated with high atmospheric pressure, high humidity and heat. There are other disorders that can lead to a condition that individuals describe by the word fatigue, for example dissatisfaction caused by emotional tension.

The exact type of rest to be prescribed for fatigue varies according to the nature of the case. In all cases, however, it is relief from strain that has to be secured, and it is often a difficult duty and a difficult thing to do, because it means very often adjusting a person to what appears to be antagonistic tendencies. Even so, if every patient with rheumatoid arthritis could at the beginning follow out a program of rest somewhat comparable to what you would advise for an early case of tuberculosis, there would probably be a good deal less of advanced arthritis. One must, however, utilize many measures to adjust the individual to all his altered physiologic conditions.

Exercise has been mentioned, it is important, and must be carried out as Dr. Krusen and Dr. Ober have indicated. Those who do best are those who persevere and follow out directions given by a physician who has optimism and who knows how to aid these patients psychologically as well as physically.

I am not going to discuss other methods of treating the various forms of chronic arthritis, but I will mention diet. There is no specific diet for arthritis. You must consider

the patient as a whole. Is he overweight, underweight? Is he by any chance allergic to any food? What is the state of his gastrointestinal tract? The problem very often becomes one of considering the whole individual's nutritional state combined with the condition of his intestinal tract, without there being any particular or specific diet. Besides a diet suitable for optimal nutrition, it is perhaps wise in certain cases to give an excess of those substances the action of which may be impaired in the face of infection, such as some vitamins and minerals.

Our aim must be to restore normal physiologic processes. Physical therapy is certainly one measure. There are others which demand attention to the patient as a whole, his mental as well as his physical status should not be neglected. Much can be accomplished by caring not only for the disease but also for the individual himself.

DR. KRUSEN (closing) I am extremely grateful to Dr. Minot and to Dr. Ober for adding to my remarks. These brilliant discussions have indicated that this subject is very complicated, and a number of important points which I was unable to cover in my presentation have been mentioned.

With regard to the institutional treatment of arthritic patients, it should be stressed that from the physical therapeutic standpoint great progress will not be made until each hospital possesses an organized department of physical therapy conducted under medical supervision. It is not the custom in modern hospitals to permit the clinical laboratory to be managed by a group of lay technicians without medical supervision. One would never think of allowing a department of roentgenology in a hospital to be under the complete supervision of a group of technicians without a medical director. Similarly, lay technicians should not be permitted to conduct a department of physical therapy without direct medical supervision. It is impossible for a lay individual to make the essential contacts with referring physicians concerning diagnosis and treatment. If physical therapy is to develop properly, there must be competent medical supervision of the departments of physical therapy in hospitals throughout the United States.

Physical therapy is a specialized field of knowledge. Despite the fact that there has been a tendency among some medical groups to consider that physical therapy is not a separate specialty and that it should be used by practicing physicians only as needed in their own particular fields, there are physicians specializing in this field of medical treatment. It is true that practically all physicians should make some use of physical therapy, leaving the more complicated procedures to the elaborately equipped departments of physical therapy in hospitals.

Although a physician may perform simple laboratory tests in his own office, he avoids doing Wassermann tests or complicated examinations of the blood in his office. A physician may utilize a small portable x-ray apparatus in his own office, but he depends, if he is wise, on the department of roentgenology in the hospital for more elaborate roentgenologic diagnosis and treatment. Thus, although a physician may use certain simple devices for physical therapy in his own office, he should rely on the specialist in that field for more elaborate methods of treatment. There can be no question that at the present time physical therapy is a specialty, and that there are many good physicians specializing in this field.

At the Mayo Clinic last year, approximately one twelfth of all the patients were referred to the Section on Physical

As Dr. Ober has pointed out, there are some patients who are more comfortable without heat. One might go even farther and point out that in certain cases patients may be benefited by applications of cold. The so-called hardening treatment (*Abhärtung*) for the patient who has arthritis may be used to relieve his abnormal sensitivity to external cold.

Dr. Ober mentioned active and passive exercise. I prefer to use the phrase 'active assistive exercise' because the patient makes an active effort to move the part and is assisted by the physician or technician in further movement. I do not agree that these movements should always be painless. If pain does not last for more than two hours after manipulation and if a flareup does not occur on the following day, as a rule the manipulation has not been too great.

Quadriceps-setting exercises are important, as stressed by Dr. Ober. The physician would do well to learn to perform this muscle setting exercise himself. It is then easier for him to show the patient how to perform it.

I have purposely avoided too much discussion of diathermy. I have reviewed this subject recently in an article which appeared in the *Journal of the American Medical Association*. Short wave diathermy, in my opinion, does not produce specific biologic or physiologic effects other than those attributable to heat. However, one may produce deeper heating with short-wave diathermy than with any other method of heating tissues, and from this standpoint it is of value. Occasionally there are cases of arthritis in which short wave diathermy may be of value, but they are few. It has been claimed that one can destroy the gonococcus *in vivo* by means of local applications of short wave diathermy. This is probably not true.

As far as can be determined, short wave diathermy is not capable of producing any great selective heating effects in the living human body, because the very efficient circulation rapidly equalizes the heat in the various tissues.

One final point which was mentioned by both Dr. Ober and Dr. Minot, and which I desire to stress, is the problem of rest. I feel that this problem is very important. In the clinic where many cases of acute arthritis are encountered, one is likely to overstress the value of rest, whereas, as Dr. Hench has pointed out, in the clinic where many chronic cases are seen, there is a likelihood that the value of exercise will be overemphasized.

At Rochester we probably see an excess of chronic cases, and therefore we may stress exercise unduly. The problem is not so much one of exercise as of mobilization. The patient should be physically rested and at the same time should have the joints mobilized. For example, the patient who has static senescent arthritis of the knee should avoid bearing weight, but the knee should be kept mobilized by means of active assistive exercises. The patient who had advanced, chronic infectious (atrophic) arthritis may awake after ten hours of sleep more fatigued than when he went to bed. This seems to indicate that rest alone is not the solution of the problem.

I am very glad that Dr. Minot mentioned relaxation and the work of Dr. Jacobson, because it would seem that routine training and relaxation should benefit certain types of patients who have arthritis. Occasionally, an intelligent patient may be told to obtain Jacobson's book for the lay man entitled *You Must Relax*.

In conclusion, I believe that this discussion has indicated definitely that the management of each patient who has arthritis is an individual problem, and usually, a most complicated one. The entire subject of the use of physical agents in the treatment of arthritis deserves much more attention than it has received in the past.

## RADIATION THERAPY IN THE TREATMENT OF INFLAMMATORY LESIONS\*

FRED O COE, M.D.†

WASHINGTON, DISTRICT OF COLUMBIA

**R**OENTGEN-RAY therapy in the treatment of inflammatory lesions has been used to some extent since the early days of x-ray, but only during more recent years has a large enough experience been gained for such therapy to command the attention that it deserves. In 1916 Dunham<sup>3</sup> published an article on the treatment of carbuncles with roentgen ray. Since that time there have been a steadily increasing number of reports of satisfactory results in treating inflammatory processes.

Acceptance of this method of treatment has probably been delayed by fear on the part of clinicians that it would result in those reactions sometimes associated with the irradiation of new growths. It should be understood that the treatment of inflammatory processes constitutes an entirely different field from that of malignant neoplasms. In the latter the aim is to give the maximum dose of radiation without irreparable damage to the underlying and surrounding structures, while in the former a very small dose is sufficient. In fact, the optimal amount of radiation is so small that it usually produces no skin changes and no appreciable untoward systemic effect. It may be stated without qualification that x-ray treatment of inflammatory lesions with proper dosage is harmless. Fortunately there is also considerable latitude to the permissible amounts and quality of radiation. The lower limit is indefinite, as there have been reports of beneficial results in mastoiditis following the routine radiographic study of the mastoids.<sup>13</sup> There is also a wide variation in the voltages which can be used—from 50,000 to 200,000 volts. Experience has proved that the upper limit of dosage should not ordinarily exceed one half an erythema unit.

Radiation therapy was at first empirical, and many diseases were treated that did not respond favorably. There was no adequate explanation of the favorable responses in certain diseases. Today it is known that lymphoid cells are the most sensitive to roentgen ray of all the cells in the body. These include the lymphocytes in the spleen, lymph nodes, circulating blood, tonsils and other structures. Such cells are destroyed by relatively

small doses of radiation. Next to the lymphocytes in sensitivity to irradiation are the polymorphonuclear leukocytes and the eosinophils. Warthin<sup>18</sup> found a rapid, almost explosive, destruction of lymphocytes within fifteen minutes after irradiation. At first thought one would not consider the destruction of lymphocytes and polymorphonuclear leukocytes to be a good therapeutic measure, as they are the productive agencies in combating disease, but in accordance with the theory of Fried,<sup>5</sup> it has been found that the destruction of leukocytes by irradiation within advisable limits apparently liberates antibodies, ferments or some bactericidal agent which brings about the prompt subsidence of the inflammation. What this substance is and how it increases phagocytosis has never been demonstrated, and the clinical results must be taken as proof of the efficacy of such treatment. That the beneficial effect is not due to direct action of the x-ray on the bacteria seems to be well proved by numerous experiments in which bacterial cultures were irradiated in vitro without destructive effects. Mohler and Taylor's experiments<sup>10</sup> show that it is very improbable that a bacterium would receive a lethal dose from the usual irradiation used in the treatment of inflammatory diseases. Desjardins<sup>1</sup> suggests that variation in effectiveness in different cases may be due to variation in the degree of the leukocytic infiltration of the offending lesion. A survey of some of the disease processes which have been cured or benefited by x-ray therapy shows that the same principle applies throughout, that is, if there is leukocytic infiltration with a high percentage of lymphocytes, irradiation alone or in conjunction with the usual therapeutic agencies such as heat or serum usually brings about a rapid termination of the disease process. In general, the more marked the inflammatory process and the earlier it is treated, the better the results.

Let us now examine the methods and results of x-ray therapy in a few of the inflammatory conditions in which it has been used in enough cases to demonstrate its value.

### PUERPERAL MASTITIS

Pfalz<sup>12</sup> in 1934 reported his experimental and clinical results in puerperal mastitis. This work

From the radiological laboratories of Drs. Crover, Christie and Merritt. Presented at the annual meeting of the Massachusetts Medical Society, Boston, June, 1935.

†Professor of radiology, Georgetown University School of Medicine, Washington, District of Columbia; radiologist to Georgetown University Hospital.

is typical of the methods used and the results obtained in the treatment of inflammation. He produced mastitis in guinea pigs by intramammary injection of *Staphylococcus aureus*. The lesions were then treated with 320 r of roentgen ray. It was found that, on the average, irradiation shortened the course of the disease and usually prevented breaking down of the tissues. Wright's opsonic and leukocytic indices were used in determining the changes in blood immunity produced by x-ray. In early infections these indices were raised after irradiation, in advanced suppuration they increased or remained constant. With this experience as a basis for treatment, Pfalz treated 41 cases of human mastitis with small doses (50 to 60 r) of x-rays. The series included both early and late cases. This method of treatment proved distinctly superior to other forms. There were no ill effects and no disturbance of lactation. We have treated a small number of cases of postpartum mastitis, and have had uniformly good results. In the cases which were referred in the early stages of the disease, there was prompt subsidence without suppuration. Unfortunately, most of the cases were referred late, the usual treatment with ice pack had already been used and the inflammation had continued to spread. Following x-ray therapy the pain increased for about six hours and then usually subsided, the process became localized, and either there was spontaneous rupture of the abscess or surgical intervention was resorted to, with drainage of the localized abscess. In all cases the referring obstetricians believed that the x-ray therapy shortened the course of the disease and localized the process. The dose given was 160 r at 112,000 volts, filtered through 3 mm of aluminum. This was repeated if necessary in three days. In no case did the treatment interfere with subsequent lactation.

#### ACUTE MASTITIS

Among 500 cases of inflammatory lesions treated there were 32 of acute mastitis. Five of these were in male adolescents. The breast and often the axillary glands were painful. Trauma was of etiologic importance in some cases. Usually there was no known predisposing factor. In none of the cases was there any suggestion of malignancy. The results of treatment were excellent, and the inflammation subsided after one to four treatments, without suppuration. A dose of 160 r was given the first day, followed by 100 r on alternate days until four treatments had been given.

#### FURUNCLES AND CARBUNCLES

X-ray therapy is especially successful in the treatment of furuncles.<sup>3, 6</sup> If the case is seen

early, before the induration is great, resolution without suppuration may be obtained in a large percentage of cases. It is also beneficial in the later stages in bringing about softening and localizations as well as prompt healing of the incision if one is necessary. The most striking effect in both furuncles and carbuncles was the quick relief from pain, nearly always within twenty-four hours and usually in six to eight. Excellent results were obtained in recurring crops of furuncles, in the absence of such underlying diseases as diabetes.

Radiation therapy is of the greatest use in furunculosis of the upper lip, nose and face. When the infection is of sufficient virulence, there is marked lymphangitis and thrombophlebitis. Infection from facial lesions not infrequently spreads early to the vessels of the brain, with a fatal termination. In our series of 27 cases there have been no such catastrophes, and all the infections have subsided without complications. If there is believed to be a mixed infection with the hemolytic streptococcus as one of the etiologic agents, the administration of sulfanilamide is advisable along with radiation therapy. The lesion should never be treated surgically. In a few cases it is necessary to give blood transfusions, especially if the process does not localize within the first twenty-four hours.

#### ERYSIPELAS

In erysipelas, streptococci localize in the connective tissue spaces and in the lymph vessels, and chiefly in the most superficial layers of the chorion. They produce a cellular exudative inflammation of the skin and subcutaneous tissues. The disease usually lasts eight to fourteen days. Many reports of successful roentgen treatment have appeared in the literature for years. We have treated many cases, in both adults and infants. Radiation is practically specific so long as the disease remains local. The dose used is 160 r at 112,000 volts through 3 mm of aluminum, not only over the entire area involved but also well beyond the margin of the lesion.

#### PNEUMONIA WITH DELAYED RESOLUTION

Musser and Edsall<sup>11</sup> in 1905, and Edsall and Peimberton<sup>4</sup> in 1907 reported on x-ray therapy in cases of delayed resolution. My associates, Drs Merritt and McPeak,<sup>9</sup> in 1930 reported on a series of such cases treated with roentgen radiation. Of the 7 cases reported, 4 underwent complete resolution, 2 were markedly improved and 1 was unchanged. We have treated many cases since the above report, with favorable results. It is believed that irradiation should be instituted if resolution does not take place at the time when it is usually ex-

pected. There have been no untoward symptoms following treatment.

#### LOBAR PNEUMONIA AND BRONCHOPNEUMONIA

Since the excellent report by Powell<sup>14</sup> on roentgen therapy of lobar pneumonia we have treated 13 cases of pneumonia with irradiation. Our results were quite as favorable as those reported by Powell. In 6 of these cases the type of pneumococcus was not reported, however all were clinically diagnosed as pneumonia, and all showed radiographic evidence of lobar consolidation. Five patients recovered either by lysis or crisis. One had consolidation on the left side which cleared rapidly after irradiation. A few days later there was a rise in temperature and a radiograph of the lungs revealed a beginning consolidation on the right side. The clinician refused to have radiation applied to this area and the patient died, this being the only death in the entire series. Of the 7 other cases, 3 were due to Type 1, 1 to Type 3, and 2 to Type 4, 1 was diagnosed as bronchopneumonia, the type not being reported. Five patients recovered by crisis and 2 by lysis. All these cases were treated with a dose of 200 to 300 r at 200,000 volts through 0.5 mm of copper, applied over the area involved. Only one treatment was required in most cases, and two in a few others. Crisis took place in most cases within twenty-four hours after treatment, and the usual course of the disease was much abbreviated. Radiation therapy is undoubtedly of marked benefit in this too common disease, and should be used more generally. We have found no harm resulting from moving the patient to the x-ray room for therapy.

#### CERVICAL ADENITIS

It has been known for many years that cases with either tuberculous or acute cervical adenitis respond to x-ray therapy.<sup>8, 14</sup> Such treatment is now well recognized as a method of choice in tuberculous adenitis, but only more recently has such treatment for adenitis accompanying the acute and chronic infections of the upper respiratory tract received wide attention. Pfahler and Kapo<sup>12</sup> in 1934 reviewed 333 cases of cervical adenitis of varying degree, both acute and chronic. They, and also their surgical colleagues, were convinced of the superior therapeutic value of roentgen irradiation. The majority of the patients were cured in from two to four treatments, with no skin atrophy and no telangiectasis. Hurwitz and Zuckerman<sup>8</sup> reported an experimental study of this method of treatment in children. Alternate cases admitted to the ward were selected for radiation treatment as the only form of local therapy. The others were treated by the usual medical

procedures,—compresses and ointments,—and served as controls. General nutritional measures were the same in each group. Only cases with marked enlargement of the lymph nodes, potentially suppurative, were included. The symptoms included fever (100°F or over), local pain at the site of the swollen nodes, anorexia, sleeplessness, irritability and occasional stiff neck. There was usually accompanying pharyngitis, tonsillitis or otitis. Staphylococci and streptococci were cultivated from the throat and nodes. The cases treated with radiation slightly outnumbered the controls because toward the end of the study, since x-ray treatment had proved obviously superior to other therapeutic measures, all patients were so treated. The authors make the following observation with regard to the immediate effect of treatment:

'One of the most striking results of roentgen therapy was the rapid improvement in the constitutional symptoms. A pronounced drop in temperature occurred in twelve to forty-eight hours with marked relief of pain and discomfort in the majority of cases. The swelling receded and resolution was complete in a shorter time than occurred when the usual medical procedures were employed. In an occasional instance, within a few hours after radiation, there was a temporary exacerbation of symptoms with increased temperature and local swelling. This reaction subsided within twelve to twenty-four hours and no untoward effects remained. With the small dose of x-rays employed, symptoms of radiation sickness, such as nausea and vomiting, were not encountered. Skin reactions did not occur.

A partial summary of the results are as follows:

'Sixty-two children with acute cervical adenitis were treated with small doses of roentgen rays. Resolution occurred in 52 (83.9 per cent) cases, while 9 (14.5 per cent) terminated in suppuration. In a group of 21 adequately controlled hospitalized patients who were irradiated, 17 (81 per cent) were cured as opposed to 10 (58.8 per cent) treated by other measures. Suppuration resulted in 3 (14.3 per cent) of the cases treated with x-rays as opposed to 7 (41.2 per cent) in the control group.

In the large series of cases we have treated, the results have been so satisfactory that all the cases at one of our hospitals are now referred for x-ray therapy. If the node becomes fluctuant, it is aspirated with aseptic technic, thus giving good cosmetic results. The dosage given is 100 to 160 r at 112,000 volts through 3 mm of aluminum. The treatment is repeated on alternate days until three have been given.

#### SINUSITIS

My associate, Dr. Rathbone,<sup>15</sup> has recently reported on the favorable results obtained in the x-ray therapy of diseases of the accessory nasal sinuses. The matter is of extreme importance because sinus disease in children is now known to be

is typical of the methods used and the results obtained in the treatment of inflammation. He produced mastitis in guinea pigs by intramammary injection of *Staphylococcus aureus*. The lesions were then treated with 320 r of roentgen ray. It was found that, on the average, irradiation shortened the course of the disease and usually prevented breaking down of the tissues. Wright's opsonic and leukocytic indices were used in determining the changes in blood immunity produced by x-ray. In early infections these indices were raised after irradiation, in advanced suppuration they increased or remained constant. With this experience as a basis for treatment, Pfalz treated 41 cases of human mastitis with small doses (50 to 60 r) of x-rays. The series included both early and late cases. This method of treatment proved distinctly superior to other forms. There were no ill effects and no disturbance of lactation. We have treated a small number of cases of postpartum mastitis, and have had uniformly good results. In the cases which were referred in the early stages of the disease, there was prompt subsidence without suppuration. Unfortunately, most of the cases were referred late, the usual treatment with ice pack had already been used and the inflammation had continued to spread. Following x-ray therapy the pain increased for about six hours and then usually subsided, the process became localized, and either there was spontaneous rupture of the abscess or surgical intervention was resorted to, with drainage of the localized abscess. In all cases the referring obstetricians believed that the x-ray therapy shortened the course of the disease and localized the process. The dose given was 160 r at 112,000 volts, filtered through 3 mm of aluminum. This was repeated if necessary in three days. In no case did the treatment interfere with subsequent lactation.

#### ACUTE MASTITIS

Among 500 cases of inflammatory lesions treated there were 32 of acute mastitis. Five of these were in male adolescents. The breast and often the axillary glands were painful. Trauma was of etiologic importance in some cases. Usually there was no known predisposing factor. In none of the cases was there any suggestion of malignancy. The results of treatment were excellent, and the inflammation subsided after one to four treatments, without suppuration. A dose of 160 r was given the first day, followed by 100 r on alternate days until four treatments had been given.

#### FURUNCLES AND CARBUNCLES

X-ray therapy is especially successful in the treatment of furuncles.<sup>3,6</sup> If the case is seen

early, before the induration is great, resolution without suppuration may be obtained in a large percentage of cases. It is also beneficial in the later stages in bringing about softening and localizations as well as prompt healing of the incision if one is necessary. The most striking effect in both furuncles and carbuncles was the quick relief from pain, nearly always within twenty-four hours and usually in six to eight. Excellent results were obtained in recurring crops of furuncles, in the absence of such underlying diseases as diabetes.

Radiation therapy is of the greatest use in furunculosis of the upper lip, nose and face. When the infection is of sufficient virulence, there is marked lymphangitis and thrombophlebitis. Infection from facial lesions not infrequently spreads early to the vessels of the brain, with a fatal termination. In our series of 27 cases there have been no such catastrophes, and all the infections have subsided without complications. If there is believed to be a mixed infection with the hemolytic streptococcus as one of the etiologic agents, the administration of sulfanilamide is advisable along with radiation therapy. The lesion should never be treated surgically. In a few cases it is necessary to give blood transfusions, especially if the process does not localize within the first twenty-four hours.

#### ERYSIPELAS

In erysipelas, streptococci localize in the connective tissue spaces and in the lymph vessels, and chiefly in the most superficial layers of the chorion. They produce a cellular exudative inflammation of the skin and subcutaneous tissues. The disease usually lasts eight to fourteen days. Many reports of successful roentgen treatment have appeared in the literature for years. We have treated many cases, in both adults and infants. Radiation is practically specific so long as the disease remains local. The dose used is 160 r at 112,000 volts through 3 mm of aluminum, not only over the entire area involved but also well beyond the margin of the lesion.

#### PNEUMONIA WITH DELAYED RESOLUTION

Musser and Edsall<sup>11</sup> in 1905, and Edsall and Pemberton<sup>4</sup> in 1907 reported on x-ray therapy in cases of delayed resolution. My associates, Drs. Merritt and McPeak,<sup>9</sup> in 1930 reported on a series of such cases treated with roentgen radiation. Of the 7 cases reported, 4 underwent complete resolution, 2 were markedly improved and 1 was unchanged. We have treated many cases since the above report, with favorable results. It is believed that irradiation should be instituted if resolution does not take place at the time when it is usually ex-

## REPORT ON MEDICAL PROGRESS

## SURGERY OF THE SYMPATHETIC NERVOUS SYSTEM

REGINALD H. SMITHWICK, MD \*

BOSTON

THE clinical importance of surgery of the sympathetic nervous system is becoming more certain from year to year. Much can now be accomplished to alleviate suffering and to improve function which was impossible even a few years ago. The full scope of this type of surgery is unknown as yet, and further progress in this field may be expected in the future.

The detailed anatomy and physiology of the sympathetic nervous system is quite complicated. Various aspects have been well described by White<sup>1</sup> and others.<sup>2,3</sup> The facts necessary for everyday clinical application may be summarized in a comparatively simple manner.

From the anatomical viewpoint, we should first realize that this system is represented by a continuous nerve trunk which lies in the paravertebral region on either side of the spinal column, and extends from the base of the skull to the end of the spine. It is divided into the cervical, thoracic, lumbar and sacral portions. Every few centimeters along its course is an enlargement, called a ganglion. There are three in the cervical portion, usually twelve in the thoracic portion, corresponding to each rib, four in the lumbar, and four or five in the sacral area.

We are concerned chiefly with the thoracic and upper lumbar areas, because it is only in these that any connection with the central nervous system exists. Thus, so-called communicating rami run between the thoracic and upper two or three lumbar ganglia and the peripheral nerves, over which impulses may pass from the central to the sympathetic nervous system or vice versa. These are known as white rami. Other rami, grey, also exist, but are of importance chiefly as a method of distributing impulses, which have already entered the previously described portion of the sympathetic nervous system, to all organs and tissues of the body, or to transmit impulses from remote areas back to the thoracolumbar portions of the sympathetic trunk. Thus it is seen that we are dealing with two pathways, first, a motor or efferent and, second, a sensory or afferent pathway. In this respect, the sympathetic nervous system can be compared to an ordinary peripheral nerve, such as the sciatic.

The motor pathway, starting in the lateral horn

of the grey matter of the spinal cord, passes out over the anterior root of an ordinary peripheral nerve, then gains the sympathetic trunk by passing over a white communicating ramus and terminates in a ganglion. It then commences again, this interruption being known as a synapse. Instead of continuing as a single fiber, however, many fibers arise which eventually terminate in some organ or tissue and pass over grey rami in their course. The first portion of this motor pathway is known as the preganglionic division, and the second as the postganglionic. One preganglionic fiber thus controls the destiny of many postganglionic fibers. This differentiation is important because we have learned from long experience that the best clinical results are obtained by interrupting the first or preganglionic rather than the second or postganglionic portion of the pathway.<sup>4,5</sup>

The sensory or afferent pathway is less complicated and has no interruption from its origin in a viscus to its termination in a posterior-root ganglion of a peripheral nerve. Moreover, the various organs of the body have a segmental reference in the spinal cord (Table 1).

TABLE 1 Location of Referred Pain \*

ORGAN	SUPERFICIAL AREA OF REFERRED PAIN	SEGMENTAL CONNECTIONS OF AFFERENT NERVE
Spinal cord (meninges)	Side of scalp and face	T 1 - T 2
Heart	Precordium and inner arm	T 1 - T 5
Esophagus	Substernal region	T 5 - T 6
Liver and gall bladder	Right upper quadrant and right scapular region	T 7 - T 8
Stomach	Epigastrium	T 7 - T 8
Small intestine	Umbilical region	T 9 - T 10
Colon	Suprapubic region	T 12 - L 2
Kidney	Loin and groin	T 12 - L 2
Ureter	Loin and groin	L 1 - L 2
Bladder	Suprapubic region	T 10 - L 2
Uterus	Suprapubic region and low back	T 12 - L 2

The tabulation varies slightly from that suggested by White.<sup>1</sup>

While the pelvic viscera have a segmental reference in the lower thoracic and upper lumbar segments of the cord, the great majority of both the motor and sensory pathways can apparently be interrupted by resection of the superior hypogastric plexus. This lies between the common iliac arteries, on the anterior surface of the body of the fifth lumbar vertebra in a retroperitoneal position.

It is helpful to think of the sympathetic network as a very complicated affair in the peripheral portions of the body, but as a much more simple affair as we approach the spinal cord. There is a 'bottle neck' through which impulses must pass

\*Assistant in surgery, Harvard Medical School; assistant visiting surgeon, Massachusetts General Hospital.

exceedingly common. The primary sinusitis is often obscured by the manifestations of recurrent colds, bronchitis, otitis media, recurrent attacks of pneumonia, bronchial asthma or cervical adenitis.

It seems certain that a considerable percentage of such cases can be cured by x-ray treatment and a certain smaller percentage greatly improved.<sup>12 13</sup> As the number of our cases increases, the more firmly are we convinced of the efficacy of the treatment, if the cases are chosen with discretion. The technic used is 100 to 120 r at 112,000 volts through 5 mm of aluminum to each area, repeated until six series of treatments have been given. The three areas used are the right and left lateral face and one anterior face.

#### SUMMARY

Cases of inflammatory diseases make up one third of all those referred to our laboratories for x-ray therapy. Their relative frequency is as follows: cervical adenitis, cellulitis, furunculosis, mastitis, sinusitis, bronchitis, carbuncle, pneumonia, breast abscess and erysipelas, with a few others of infrequent occurrence.

X-ray therapy of inflammatory diseases has proved a valuable and safe agent in the hands of qualified radiologists and its field of use is being extended daily. The best results can be achieved when there is a close co-operation between the referring doctor and the radiologist in the management of all such cases.

#### DISCUSSION

DR JACK SPENCER, Boston. This stimulating paper again reminds us of the value of x-ray treatment of certain infections. We have all seen the striking action of x-ray treatment of erysipelas, and the efficacy of radiation in the treatment of infections about the nose. These are now appreciated to such an extent that practically all early cases are treated by x-ray. Postoperative parotitis may be added. In this group of cases the mortality has been decreased from 60 per cent where radiation is not used to about 20 per cent where it is.

The success in the use of this valuable adjunct to the treatment of infections should make us realize the importance of familiarizing ourselves and our associates with its worth, not only in this group where one of the most important therapeutic agents is radiation therapy, but also in that large group of cases discussed in this paper, where x-ray treatment is a valuable adjunct. As stated, one third of the cases in the reader's clinic were referred for radiation of inflammatory lesions.

I am pleased to learn that Dr. Coe and his associates are so conservative with their roentgen doses, giving from one third to one half of a skin erythema dose, thus avoiding any possibility whatsoever of skin changes.

We have all profited by this paper, which contains a wealth of information. I am sure it is a stimulus to us to use radiation in more of the infections which we see.

## REPORT ON MEDICAL PROGRESS

## SURGERY OF THE SYMPATHETIC NERVOUS SYSTEM

REGINALD H SMITHWICK, M.D \*

BOSTON

THE clinical importance of surgery of the sympathetic nervous system is becoming more certain from year to year. Much can now be accomplished to alleviate suffering and to improve function which was impossible even a few years ago. The full scope of this type of surgery is unknown as yet, and further progress in this field may be expected in the future.

The detailed anatomy and physiology of the sympathetic nervous system is quite complicated. Various aspects have been well described by White<sup>1</sup> and others.<sup>2,3</sup> The facts necessary for everyday clinical application may be summarized in a comparatively simple manner.

From the anatomical viewpoint, we should first realize that this system is represented by a continuous nerve trunk which lies in the paravertebral region on either side of the spinal column, and extends from the base of the skull to the end of the spine. It is divided into the cervical, thoracic, lumbar and sacral portions. Every few centumeters along its course is an enlargement, called a ganglion. There are three in the cervical region, usually twelve in the thoracic portion, corresponding to each rib, four in the lumbar, and four or five in the sacral area.

We are concerned chiefly with the thoracic and upper lumbar areas, because it is only in these that any connection with the central nervous system exists. Thus, so-called communicating rami run between the thoracic and upper two or three lumbar ganglia and the peripheral nerves, over which impulses may pass from the central to the sympathetic nervous system or vice versa. These are known as white rami. Other rami, grey, also exist, but are of importance chiefly as a method of distributing impulses, which have already entered the previously described portion of the sympathetic nervous system, to all organs and tissues of the body, or to transmit impulses from remote areas back to the thoracolumbar portions of the sympathetic trunk. Thus it is seen that we are dealing with two pathways, first, a motor or efferent and, second, a sensory or afferent pathway. In this respect, the sympathetic nervous system can be compared to an ordinary peripheral nerve, such as the sciatic.

The motor pathway, starting in the lateral horn

of the grey matter of the spinal cord, passes out over the anterior root of an ordinary peripheral nerve, then gains the sympathetic trunk by passing over a white communicating ramus and terminates in a ganglion. It then commences again, this interruption being known as a synapse. Instead of continuing as a single fiber, however, many fibers arise which eventually terminate in some organ or tissue and pass over grey rami in their course. The first portion of this motor pathway is known as the preganglionic division, and the second as the postganglionic. One preganglionic fiber thus controls the destiny of many postganglionic fibers. This differentiation is important because we have learned from long experience that the best clinical results are obtained by interrupting the first or preganglionic rather than the second or postganglionic portion of the pathway.<sup>4,5</sup>

The sensory or afferent pathway is less complicated and has no interruption from its origin in a viscus to its termination in a posterior-root ganglion of a peripheral nerve. Moreover, the various organs of the body have a segmental reference in the spinal cord (Table 1).

TABLE 1 Location of Referred Pain \*

ORGAN	SUPERFICIAL AREA OF REFERRED PAIN	SEGMENTAL CONNECTION OF AFFERENT NEURONES
Spinal cord (meninges)	Side of scalp and face	T 1 - T 2
Heart	Precordium and inner arm	T 1 - T 5
Esophagus	Substernal region	T 5 - T 6
Liver and gall bladder	Right upper quadrant and right scapular region	T 7 - T 8
Stomach	Epigastrium	T 7 - T 8
Small intestine	Umbilical region	T 9 - T 10
Colon	Suprapubic region	T 12 - L 2
Kidney	Loin and groin	T 12 - L 2
Ureter	Loin and groin	L 1 - L 2
Bladder	Suprapubic region	T 10 - L 2
Uterus	Suprapubic region and low back	T 12 - L 2

The tabulation varies slightly from that suggested by White.<sup>1</sup>

While the pelvic viscera have a segmental reference in the lower thoracic and upper lumbar segments of the cord, the great majority of both the motor and sensory pathways can apparently be interrupted by resection of the superior hypogastric plexus. This lies between the common iliac arteries, on the anterior surface of the body of the fifth lumbar vertebra in a retroperitoneal position.

It is helpful to think of the sympathetic network as a very complicated affair in the peripheral portions of the body, but as a much more simple affair as we approach the spinal cord. There is a bottle neck through which impulses must pass

#### DISCUSSION

DR. JACK SPENCER, Boston. This stimulating paper again reminds us of the value of x-ray treatment of certain infections. We have all seen the striking action of x-ray treatment of erysipelas, and the efficacy of radiation in the treatment of infections about the nose. These are now appreciated to such an extent that practically all early cases are treated by x-ray. Postoperative parotitis may be added. In this group of cases the mortality has been decreased from 60 per cent where radiation is not used to about 20 per cent where it is.

The success in the use of this valuable adjunct to the treatment of infections should make us realize the importance of familiarizing ourselves and our associates with its worth, not only in this group where one of the most important therapeutic agents is radiation therapy, but also in that large group of cases discussed in this paper, where x-ray treatment is a valuable adjunct. As stated, one third of the cases in the reader's clinic were referred for radiation of inflammatory lesions.

I am pleased to learn that Dr. Coe and his associates are so conservative with their roentgen doses, giving from one third to one half of a skin erythema dose, thus avoiding any possibility whatsoever of skin changes.

We have all profited by this paper, which contains a wealth of information. I am sure it is a stimulus to us to use radiation in more of the infections which we see.

be neurogenic in origin. There appears to be an improper balance between the sympathetic (inhibitory) and the parasympathetic (motor) innervation of the colon. Beneficial results have been reported following lumbar sympathectomy when the imbalance is chiefly confined to the left colon. Resection of the splanchnic nerves as well may be necessary if the right colon is involved.<sup>8</sup>

*Essential Hypertension* Surgical attempts to alleviate high blood pressure of unknown etiology have stimulated widespread interest in this problem. The internist,<sup>9</sup> the surgeon and the physiologist<sup>10-11</sup> are all concerned themselves with the study of essential hypertension. As a result of such combined effort, it is to be hoped that a clear understanding of the nature of this malady will result.

Sporadic attempts to lower blood pressure by sympathectomy have been made in the past,<sup>12</sup> but most of the cases are of only a few years' duration, so that the results are difficult to analyze. A number of operations<sup>12-13</sup> have been devised, the purpose and the effects of which are similar.<sup>12-24</sup>

It is commonly thought that high blood pressure is due to increased peripheral resistance to blood flow. By sympathectomy, this resistance is presumably decreased so that a lower blood pressure level results.

It has been shown that significant blood-pressure changes follow extensive sympathetic denervation of the splanchnic bed and that a normal blood-pressure level may result from such an operation without harm to any organs or tissues of the body, and with relief of distressing symptoms which may result from high blood-pressure levels. This effect may be lasting, and many patients have had normal blood-pressure levels for from two to six years after such a procedure. It has been demonstrated that the best results are obtained in young age groups with variable blood pressure levels and with minimal evidence of organic changes in the eyes, heart and kidneys.

Even under these circumstances the results are not uniform. Moreover, our experience during the past five years shows that results as described above are obtained only in 40 to 50 per cent of the favorable cases. The experience of others is similar. In the groups with advanced organic vascular changes, a material lowering in blood-pressure levels can be expected in only 5 or 10 per cent of the cases although symptomatic relief may be marked.

The surgical attack on this disease must still be regarded as in an experimental stage. It takes many years of trial and error to determine the most effective method of denervating any portion of the

vascular bed, and the lack of uniformity of results in identical cases leads one to suspect that this has not as yet been accomplished with regard to the splanchnic bed. Further observation of late results will be necessary to determine the indications for and the true value of sympathetic surgery for this disease.

#### SURGERY OF THE SENSORY PATHWAYS

A knowledge of the sensory pathways from various organs to the central nervous system and of their segmental reference in the spinal cord is of primary importance because of its diagnostic possibilities. In this way one can explain why pain arising in an organ as the result of what happens to be an adequate stimulus for that particular viscus will be felt by the patient in a certain region. It is often referred peripherally over a number of segments adjacent to the white ramus over which the impulse passes to reach the posterior root ganglia. Tension is the usual stimulus which results in visceral pain. In the case of peripheral arteries and muscles the stimulus is probably the result of increased concentration of acid metabolites in the tissues.

*Pain in the Head, Face and Arms* One is occasionally confronted with the problem of pain in the head, face and arms, and the afferent sympathetic pathways are often concerned. That this is the case, can be determined by diagnostic paravertebral novocain block of the upper two or three thoracic segments. It is interesting to note that when relief from novocain alone is immediate and striking, it may last for weeks or months. Permanent relief of atypical neuralgias of the head and face may follow resection of the inferior cervical and upper two dorsal sympathetic ganglia.

*Causalgia* Following injuries or infections of the hand, an exceedingly painful causalgia may result. These cases present most distressing problems. As a rule, both motor and sensory sympathetic pathways are involved, as well as the somatic sensory nerves. There may also be a local fault in the form of scar tissue, a neuroma or an unsatisfactory amputation stump. In some instances sympathectomy may have to be combined with excision of local scar tissue and resection of the peripheral sensory nerves. A similar lesion of the lower extremity is occasionally seen.

*Angina Pectoris* Paravertebral alcohol injection of the upper four or five dorsal segments on one or both sides, as indicated by the distribution of referred pain, has resulted in lasting and satisfactory relief of pain in cases of intractable angina pectoris. In skillful hands, practically complete re-

to and from any particular part of the body in order to leave or enter the central nervous system. The problem is to find the "bottle neck." In many instances this is now known beyond any doubt, in others we are in the process of learning. It seems certain however, that if the correct operation is performed, excellent and lasting effects can be obtained.

We now believe that interruption of sympathetic pathways is indicated in a number of well-recognized clinical conditions. These are best divided into two groups, depending on whether the motor or sensory pathway is concerned.

The result to be expected in any case can be determined by preliminary study. Both motor and sensory pathways can be blocked temporarily by novocain in a number of ways.<sup>1</sup> Other important tests are also utilized. Space does not allow a discussion of these. One should understand, however, that operation is not undertaken unless it has first been demonstrated that the effect will be beneficial.

#### SURGERY OF THE MOTOR PATHWAYS

*Peripheral Vascular Disease* By far the largest general field of application for surgery of the motor pathway is in the treatment of peripheral vascular disease. Many patients suffer from inadequate blood flow to the extremities for a variety of reasons. In some cases, decreased circulation may be largely the result of vascular spasm, as in Raynaud's disease and allied disorders. In others, obliteration of the main vessels is present, and the element of spasm is minimal or absent. Arteriosclerosis with associated diabetes is an example. Other patients suffer from a combination of obliterative vascular disease and vascular spasm, such as is found in thromboangitis obliterans or Buerger's disease. When vascular spasm alone is present, brilliant results may be expected from a properly executed sympathectomy. When obliteration of main vessels is the cause of impaired circulation and spasm is absent, interruption of sympathetic pathways is not helpful and is not indicated. When a combination of the two factors is present, sympathectomy may be indicated and, if so, usually results in an improved circulation which is lasting and beneficial.

Most cases of peripheral vascular disease may be fitted into one of these three groups as a result of clinical study and tests designed to determine the amount of vascular spasm which may be present.

*Anterior Poliomyelitis* Impaired circulation to the lower extremities may follow infantile paralysis. This situation, of course, is not to be grouped among primary vascular diseases, and is compli-

cated by extreme muscular weakness, atrophy and diminished blood flow to the skin and subcutaneous tissues. In extreme examples with cold, moist, cyanotic, ulcerated extremities, sympathectomy may be indicated. If properly done, the results have been helpful.

*Hyperhidrosis* Distressing examples of hyperhidrosis may be completely relieved by sympathectomy. There are occasional individuals who suffer from excessive perspiration which may involve all four extremities and cannot be controlled by medical measures. When present to this degree, it may be a great occupational and psychological handicap. Interruption of sympathetic pathways to such extremities causes complete abolition of sweating, as well as a vasomotor paralysis, and the results are regarded as extremely satisfactory by these patients.

*Sudden Arterial Occlusion* Sympathectomy may be an important adjunct to other forms of therapy in the case of sudden occlusion of peripheral arteries. This may be the result of embolism or thrombosis. It may be associated with primary disease of the peripheral artery or may, in the case of the upper extremity, be complicated by cervical ribs, anomalous first ribs or the scalenus anticus syndrome. The primary lesion should receive first consideration, but we realize that vascular spasm plays an important secondary role. If eradication of the primary lesion does not relieve the secondary spasm, or if the primary lesion is not amenable to surgical approach, sympathectomy may be indicated. Space does not permit an adequate discussion of this important group of cases.

*Sympathetic Surgery of the Extremities* The technic of operations designed to cause sympathetic denervation of the extremities has been reported in detail.<sup>6-7</sup> In general it may be said that these procedures carry a minimal risk (a fraction of 1 per cent) and a short period of disability, and are now very well standardized. It seems unlikely that there will be any essential variations from the present technic in the future. Surgical excision of appropriate areas is the procedure of choice.

Paravertebral alcohol injection may be utilized as an alternative method. This is distinctly a second choice, as the results are usually incomplete, are not permanent and may be followed by distressing and prolonged peripheral neuritis, and so far as the motor pathway is concerned, such injections are done only when the general condition of the patient or the benefit to be gained does not appear to justify the operation of choice.

*Hirschsprung's Disease* Congenital dilatation of the colon (Hirschsprung's disease) is believed to

hief of pain should result in 75 per cent of cases and moderate relief in 10 or 15 per cent, while failures should not occur in over 10 per cent. This procedure carries a low mortality rate (1 to 2 per cent) as contrasted with a rate of 25 per cent as the result of operative procedures of any magnitude. Painful peripheral neuritis lasting several weeks usually follows the injection. Aortic-arch pain due to aneurysms may be treated in a similar manner, and the results have been extremely satisfactory.

*Pain from Abdominal Viscera.* One is rarely called on to treat referred pain from abdominal viscera. As a rule, abdominal surgery for the lesion itself is indicated. However, in the case of severe pain referred to a given area from extensive cancer, such as lesions in the liver, relief may be obtained by paravertebral alcohol injection.

We have had several occasions to treat referred pain arising from the biliary and upper gastrointestinal tracts by paravertebral alcohol injections or splanchnic resection. In these particular cases the results were most satisfactory. In one, repeated operations on the common duct failed to relieve severe colic, which was later controlled by resection of the right splanchnic nerves. In two others, severe referred pain from posterior-wall, penetrating, duodenal ulcers was relieved by paravertebral alcohol injection, as the condition of the patients did not justify eradication of the lesion itself.

*Genitourinary-Tract Pain.* In certain cases sympathectomy may be helpful in dealing with problems involving the genitourinary tract. This is particularly true of the relief of pain, although some improvement in abnormal motor function of the bladder may be expected under the proper circumstances.

The bladder has a triple nerve supply, and it is the function of the sympathetic portion to permit filling of this organ. Sympathetic impulses cause relaxation of the bladder wall and contraction of the internal sphincter. Parasympathetic impulses produce the opposite effect. When the latter pathway is damaged, inability to empty the bladder results in a large residual and, later, damage to the kidneys from back-pressure and infection. Under such circumstances, resection of the sympathetic supply by excision of the superior hypogastric plexus has given good clinical results. One should be certain, however, that the third source of nerve supply—the somatic nerves arising from the third and fourth sacral segments—is intact, as paralysis of the external sphincter con-

traindicates excision of the sympathetic nerves. The information necessary to make a decision in a given case can be obtained by a combination of cystoscopy and paravertebral novocain block.

Renal and ureteral colics of unknown etiology have been relieved by interruption of the afferent sympathetic pathways. The kidney itself can be denervated by careful resection of the sympathetic plexus about the renal vessels. Ureteral pain has been relieved by dividing its nerve supply throughout its length and by displacing the ureter laterally to aid in preventing regeneration. Lumbar sympathectomy should also help in such cases.

Bladder pain is a more complicated matter, as the sensory nerves pass over three different pathways—the sympathetic, parasympathetic and somatic. The sympathetic pathway is perhaps the least important, and for this reason resection of the superior hypogastric plexus alone has not yielded very satisfactory results in the treatment of such conditions as tuberculous cystitis, interstitial cystitis and cancer, except where the lesions are chiefly confined to the trigone and about the ureteral orifice. Resection of the superior hypogastric plexus and removal of the upper three sacral ganglia, combined with carefully controlled intrathecal alcohol injections, have given good results in a variety of painful bladder conditions.<sup>5</sup> It must be emphasized that resection of the superior hypogastric plexus in men may result in inability to ejaculate and consequent sterility.

Very satisfactory results have been obtained by resection of the superior hypogastric plexus for dysmenorrhea. This should, of course, be done only in the most intractable cases. Resection was first suggested by Cotte<sup>20, 21</sup> and has proved satisfactory in the hands of others. Meigs<sup>22</sup> has contrasted the results in 20 cases in which resection alone was done with those in 7 cases in which other procedures such as dilatation of the cervix and suspension of the uterus were carried out in addition to resection. In the first group satisfactory results were obtained in 75 per cent of the cases, while in the second group, complete relief of symptoms followed in all but 1 patient. Sufficient observations are on record so that it may be stated that no material change in the menstrual cycle follows, and pregnancy and parturition are not affected by this operation. Satisfactory relief of pain also followed this operation in cases of advanced cancer of the cervix and uterus in which bony metastases and involvement of pelvic nerves had not taken place.

lief of pain should result in 75 per cent of cases and moderate relief in 10 or 15 per cent, while failures should not occur in over 10 per cent. This procedure carries a low mortality rate (1 to 2 per cent) as contrasted with a rate of 25 per cent as the result of operative procedures of any magnitude. Painful peripheral neuritis lasting several weeks usually follows the injection. Aortic-arch pain due to aneurysms may be treated in a similar manner, and the results have been extremely satisfactory.

*Pain from Abdominal Viscera.* One is rarely called on to treat referred pain from abdominal viscera. As a rule, abdominal surgery for the lesion itself is indicated. However, in the case of severe pain referred to a given area from extensive cancer, such as lesions in the liver, relief may be obtained by paravertebral alcohol injection.

We have had several occasions to treat referred pain arising from the biliary and upper gastrointestinal tracts by paravertebral alcohol injections or splanchnic resection. In these particular cases the results were most satisfactory. In one, repeated operations on the common duct failed to relieve severe colic, which was later controlled by resection of the right splanchnic nerves. In two others, severe referred pain from posterior-wall, penetrating, duodenal ulcers was relieved by paravertebral alcohol injection, as the condition of the patients did not justify eradication of the lesion itself.

*Genitourinary-Tract Pain.* In certain cases sympathectomy may be helpful in dealing with problems involving the genitourinary tract. This is particularly true of the relief of pain, although some improvement in abnormal motor function of the bladder may be expected under the proper circumstances.

The bladder has a triple nerve supply, and it is the function of the sympathetic portion to permit filling of this organ. Sympathetic impulses cause relaxation of the bladder wall and contraction of the internal sphincter. Parasympathetic impulses produce the opposite effect. When the latter pathway is damaged, inability to empty the bladder results in a large residual and, later, damage to the kidneys from back-pressure and infection. Under such circumstances, resection of the sympathetic supply by excision of the superior hypogastric plexus has given good clinical results. One should be certain, however, that the third source of nerve supply—the somatic nerves arising from the third and fourth sacral segments—is intact, as paralysis of the external sphincter con-

traindicates excision of the sympathetic nerves. The information necessary to make a decision in a given case can be obtained by a combination of cystoscopy and paravertebral novocain block.

Renal and ureteral colics of unknown etiology have been relieved by interruption of the afferent sympathetic pathways. The kidney itself can be denervated by careful resection of the sympathetic plexus about the renal vessels. Ureteral pain has been relieved by dividing its nerve supply throughout its length and by displacing the ureter laterally to aid in preventing regeneration. Lumbar sympathectomy should also help in such cases.

Bladder pain is a more complicated matter, as the sensory nerves pass over three different pathways—the sympathetic, parasympathetic and somatic. The sympathetic pathway is perhaps the least important, and for this reason resection of the superior hypogastric plexus alone has not yielded very satisfactory results in the treatment of such conditions as tuberculous cystitis, interstitial cystitis and cancer, except where the lesions are chiefly confined to the trigone and about the ureteral orifice. Resection of the superior hypogastric plexus and removal of the upper three sacral ganglia, combined with carefully controlled intrathecal alcohol injections, have given good results in a variety of painful bladder conditions.<sup>2</sup> It must be emphasized that resection of the superior hypogastric plexus in men may result in inability to ejaculate and consequent sterility.

Very satisfactory results have been obtained by resection of the superior hypogastric plexus for dysmenorrhea. This should, of course, be done only in the most intractable cases. Resection was first suggested by Cotte<sup>20</sup> and has proved satisfactory in the hands of others. Meigs<sup>28</sup> has contrasted the results in 20 cases in which resection alone was done with those in 7 cases in which other procedures such as dilatation of the cervix and suspension of the uterus were carried out in addition to resection. In the first group, satisfactory results were obtained in 75 per cent of the cases, while in the second group, complete relief of symptoms followed in all but 1 patient. Sufficient observations are on record so that it may be stated that no material change in the menstrual cycle follows, and pregnancy and parturition are not affected by this operation. Satisfactory relief of pain also followed this operation in cases of advanced cancer of the cervix and uterus in which bony metastases and involvement of pelvic nerves had not taken place.

of shaking chills and fever. At 4 a m he vomited approximately a pint of dark-brown material. At 5:30 a m he suddenly experienced a sharp pain beginning in his right side, extending across the right upper quadrant beneath the costal margin to the epigastrium. The pain lasted about five minutes, but soreness remained in this area. Similar attacks of pain recurred throughout the day and in the afternoon he vomited clots of blood. There had been no change in weight since the last admission.

Physical examination revealed a slightly pale man in no distress. There was no dyspnea or cyanosis. Examination of the lungs was normal. The heart sounds were normal in rate, rhythm and quality. The blood pressure was 120 systolic, 60 diastolic. The abdomen was soft, and peristalsis sluggish. An indefinite mass was present in the left lower quadrant which was tender just to the left of and below the umbilicus. Rectal examination revealed a symmetrically enlarged prostate.

The temperature was 98.6°F, pulse 80, respirations 20.

The urine examination was negative. The blood showed a red-cell count of 3,170,000 with 75 per cent hemoglobin and a white-cell count of 13,000 with 81 per cent polymorphonuclears. There was considerable variation in the size of the red cells. A blood Hinton test was negative. The nonprotein nitrogen of the serum was 59 mg per cent. Four stool examinations were guaiac positive.

A barium enema examination showed that the sigmoid looped high out of the pelvis and remained fixed in that position. There was an impression that there was an extrinsic tumor posterior to the sigmoid in this area, although no definite tumor mass could be made out on the film. The remaining colon and cecum were normal.

On the third hospital day a gastrointestinal x-ray series showed a large amount of barium in the colon from the previous examination. The appendix was filled at this time. The hepatic flexure partially obscured the region of the duodenal cap. As far as could be told there was no evidence of abnormality in the stomach or duodenum. An intravenous pyelogram was negative. Four days later a repeat gastrointestinal series was essentially the same as the previous one. The stomach was high, the duodenum pointed posteriorly and was rather difficult to examine. On the seventh hospital day the temperature rose from normal to 102°F., and on the eighth day to 103°F. then returned to normal. Respirations remained at 20. On the eleventh hospital day a cystoscopic examination showed a normal bladder and no significant enlargement of the prostate. The following day gastroscopy showed a normal stomach.

The pylorus was not seen. Two days later the temperature rose sharply to 103°F., respirations to 30. The right arm was swollen and hot. On the fifteenth hospital day the patient was moribund. There was dullness at the right lung base and numerous crackling rales. Rales were also present over the left base. An indefinite mass was palpated in the left lower quadrant, and pressure over this area caused pain. A blood culture showed hemolytic streptococci. The patient rapidly failed and died on the sixteenth hospital day.

#### DIFFERENTIAL DIAGNOSIS

DR. F. DENNETTE ADAMS. The two admissions to the hospital will be discussed separately. At the first admission four important symptoms require explanation: (1) vomiting of blood, (2) pain, (3) increasing constipation, (4) loss of weight occurring in spite of a presumably adequate diet.

The pain is of the obstructive type. Its distribution is most suggestive of an obstructive lesion in the colon, a hypothesis which is further borne out by the fact that the patient was aware of a "lump" in the right upper quadrant which, along with the pain, would disappear following a bowel movement or passage of gas.

Hematemesis most commonly results from peptic ulcer, gastritis, esophageal varices, gastric polyp, or cancer. The history is not suggestive of peptic ulcer or gastritis, although either sometimes exists without characteristic pain related to food intake. Nor are there any symptoms to make one suspicious of cirrhosis of the liver with resultant esophageal varices. Gastric polyp might be a cause of the bleeding but would not explain pain of this character.

If then, we rely on history alone—that is all we are considering at this point—the most plausible explanation of the illness is cancer of the stomach. Increasing epigastric pain, loss of weight, hematemesis and increasing constipation are all readily explainable on this basis, involvement of the colon with partial obstruction could be due to extension of the tumor with invasion of the transverse colon.

Physical examination contributes very little. The harsh systolic murmur at the base may indicate calcareous disease of the aortic valve with some degree of stenosis, but the evidence is inconclusive. Nothing is said about a thrill, or diminution of the aortic second sound. The pulse pressure of 80 is decidedly against aortic stenosis, one of 20 or 30 would be more convincing. Absence of a palpable mass does not necessarily exclude cancer of the stomach, but one would hardly expect the patient to have a gastric cancer sufficiently extensive to involve the transverse colon.

## CASE 25111

### PRESENTATION OF CASE

*First Admission* A seventy-two-year-old married English farmer was admitted complaining of abdominal pain.

About six months before admission the patient began having attacks of cramp-like pain in the right lower quadrant which seemed to move slowly upward to the right upper quadrant. These attacks lasted about five minutes and occurred at one- to five-day intervals. They were always relieved by defecation or the passage of gas. During these six months he also had epigastric distress with a feeling of fullness accompanied by belching and sometimes regurgitation of sour material. This distress usually came on after breakfast and was somewhat relieved by taking soda. At times he had mild, non-radiating epigastric pain. Occasionally he also noted a "lump" in the right upper quadrant which would disappear after the pain had gone. On some occasions the pain was made worse by food and relieved by soda. There was no definite relation to meals or to the type of food eaten. During the past year he had been constipated whereas previously his bowel movements had been regular. At times during the last six months he had noticed dark stools and on a few occasions a small amount of bright-red blood. He stated that his appetite had been poor for a year but that until recently he had eaten about the same amount that he always had. He felt that he had lost a considerable amount of weight during the last six months, but had not actually weighed himself. Five days before entry he felt somewhat nauseated and vomited about a half cupful of bright-red blood. He had not vomited previously. Later the same day he vomited some very dark, thick fluid. During the next two days he vomited a similar material. There was no emesis during the last two days although he felt nauseated. He had not had severe right upper-quadrant pain, icterus or clay-colored stools. There had been no abdominal tenderness or swelling and no pain that awakened him at night. His past and family histories were noncontributory.

Physical examination showed an obese elderly man in no distress. Examination of the lungs was

normal. The heart did not seem to be enlarged. There was a harsh systolic murmur loudest over the aortic area.  $A_2$  was louder than  $P_2$ . The blood pressure was 148 systolic, 68 diastolic. The abdomen was soft and no masses or tenderness could be made out. By rectal examination the prostate was twice its normal size, but symmetrical and non-tender.

The temperature was 99°F, the pulse 100, respirations 24.

The urine examination was negative except for the presence of 10 to 15 white cells per high power field. The blood showed a red-cell count of 2,600,000 with 50 per cent hemoglobin, and a white-cell count of 7600 with 76 per cent polymorphonuclears. There was marked anisocytosis and many of the red cells were large, though all were well filled with hemoglobin. The volume index was 1, the color index 1. A blood Hinton test was negative. A bromsulfalein test of liver function showed 0 to 5 per cent retention. A Takata-Ara test was negative. Three gastric analyses showed free acid varying from 27 to 94 units, total acid from 67 to 100 units. One stool examination was guaiac positive, another guaiac negative.

A barium enema x-ray examination showed a large pressure defect for a distance of 20 to 25 cm in the sigmoid, due to a large "tumor" in the pelvis, apparently a full bladder. The remainder of the examination of the colon was negative. A gastrointestinal x-ray series showed a normal esophagus and a high stomach but was otherwise negative. Hourly follow-up films of the small intestine showed no abnormality aside from pressure on the lower loops of ileum apparently due to a filled urinary bladder.

On the fifth hospital day a Graham test was negative. The following day a proctoscope was passed a distance of 21 cm showing no obstruction. The rectal mucous membrane was granular and definitely pigmented. No cancer or ulcers were seen. During the next few days the patient felt well and his bowel movements were normal. He was discharged on the fourteenth hospital day.

*Final Admission* (six months later) Since discharge he had felt fairly well except for occasional mild attacks of epigastric burning sensations relieved by milk and crackers. He had had a few attacks of right upper-quadrant and epigastric pain associated with vomiting of small amounts of dark blood. These attacks passed off readily leaving only slight soreness in the epigastrium. Two days before admission he suddenly became nauseated about 9 p.m. and vomited, but there was no blood in the vomitus and he had no pain. From 10 p.m. to 4 a.m. he was unable to sleep because

of shaking chills and fever" Probably he did not have a true chill but only the chilly sensations which almost always accompany onset of fever

There is nothing in the second admission to influence me to change my diagnosis The gastroscopy ruled out even more completely cancer of the stomach, gastritis, and the less likely possibility of ulcer of the stomach It could not rule out ulcer of the duodenum

Why did the man die? The episode of chills, fever, and severe pain suggests perforation and of course, if he perforated something, it was undoubtedly the ulcerative lesion which we assume to be present Perhaps the process was sufficiently walled off to prevent general peritonitis Even so, he may have had general peritonitis for we know this condition can exist in debilitated patients without producing the usual picture In this case it is unlikely because of the interval of time between the onset of the acute episode and death Septicemia, secondary to perforation, embolic pneumonia, and an embolic lesion in the arm are the likely terminal features

The most plausible explanation which I can give of this man's illness is that he had malignant lymphoma causing an ulcerative lesion of the upper part of the intestinal tract, perhaps the lower duodenum or the upper jejunum, and enlargement of abdominal lymph nodes, and that he died of septicemia secondary to perforation of the ulcerative lesion Calcereous aortic disease may have been present but is of only secondary importance

DR. MALLORY On reading over the history as given to Dr Adams I found myself quite unable to make a diagnosis and yet the autopsy permission was filled out with the correct diagnosis when it came over to us I would be interested to know how they did it

DR. RALPH ADAMS An explanation should be made Everyone saw this patient from the senior surgeon of the hospital down to the house student The only one who had not seen the patient, and incidentally the youngest man on the service, saw him at three o'clock in the morning when he was discharging him to your department, read the history, and was the only person who made a correct diagnosis

#### CLINICAL DIAGNOSES

Malignant tumor of large intestine.  
Pulmonary infarcts  
Bronchopneumonia

#### DR. ADAMS'S DIAGNOSES

Malignant lymphoma with an ulcerative lesion of the upper part of the small intestine and involvement of abdominal lymph nodes  
General septicemia  
Septic bronchopneumonia  
Embolic infarct of the arm

#### ANATOMICAL DIAGNOSES

Duodenal ulcer, chronic  
Pulmonary atelectasis  
Melanosis coli  
Meningioma  
Basophilic adenoma of pituitary

#### PATHOLOGICAL DISCUSSION

DR. MALLORY The autopsy showed only one lesion of any significance That was a typical chronic duodenal ulcer The terminal episode was septicemia undoubtedly from phlebitis in the arm There was no mass anywhere in the lower abdomen The prostate was not significantly enlarged, the bladder was perfectly normal There was nothing in the lower intestinal tract

A PHYSICIAN Was the phlebitis possibly secondary to therapy?

DR. RALPH ADAMS It so happened he had not had an intravenous in that arm He had had one in the other arm

DR. RICHARD SCHATZKI Did he have multiple pulmonary infarcts?

DR. MALLORY No, foci of atelectasis and minimal bronchopneumonia

DR. F. DENNETTE ADAMS Had he no perforation?

DR. MALLORY No

DR. ADAMS Dr Mallory, what is the significance of the pigmentation of rectal mucosa noted on proctoscopic examination?

DR. MALLORY It was characteristic melanosis coli This is common in the seventies, very common in the eighties and, in my experience, universal in the nineties

I should, perhaps, for the sake of completeness mention two other findings There was a small meningioma of the dura, and microscopic sections of the pituitary show a small basophilic adenoma Certainly neither of them produced overt clinical symptoms, but one might speculate on their etiologic relation to the ulcer

without its being palpable. The prostate is large but is not described as being hard or asymmetrical, which is the usual story with carcinoma of this gland.

The blood count is consistent with anemia secondary to hemorrhage, although one would expect a low volume index and low color index. The polymorphonuclear count is relatively high. The normal liver function and Takata-Ara tests are added evidence against cirrhosis of the liver. The high gastric acidity is definitely against cancer of the stomach and, taken into consideration with the negative x-ray, seems to exclude this disease.

It now becomes necessary to look elsewhere for a solution of this problem and when we seek help from the roentgenologist we are further confused by being forced to account for a mass in the lower abdomen in addition to the symptoms referable to the upper abdomen. The roentgenologist's observation that a mass is present is doubtless correct, but I question his interpretation for these reasons: (1) An acutely distended bladder should cause lower abdominal discomfort or pain and probably a story of inability to void. (2) A chronically distended bladder secondary to obstruction, or a diverticulum of the bladder would probably cause some urinary symptom such as frequency and certainly an infected urine. Neither is reported in this case. What, then, are the diagnostic possibilities? The lower abdominal mass, judging from the roentgenologic appearance, is not an intrinsic tumor, so we can exclude cancer and multiple polyps of the lower bowel. The latter are further excluded by the proctoscopic examination, for, when multiple polyps are present, one or more can usually be seen. There is nothing to suggest diverticulitis with abscess. Furthermore, none of these disorders can account for the hematemesis. I do not know the significance of the pigmentation and the granular appearance of the rectal mucosa. Pigmentation is sometimes due to prolonged use of cascara.

Perhaps Dr. Holmes will demonstrate the x-rays.

DR. GEORGE W. HOLMES: In a case of this kind with so many films it is almost impossible to give intelligent information on short notice. In the records there is no statement that anything very definite was found. This film shows an appearance in the sigmoid which is sometimes seen when gut is stretched over a mass, and I would agree with what has been said, that the mass lies outside the colon and that the colon may be adherent to it or stretched over it. We have no evidence that there was a mass in the small bowel, but it is well known that a large mass may be present without producing obstruction, and unless

the examiner happens to make his observation at the time the barium is passing through the involved region it may be missed. Apparently that was thought of and a careful study done to rule out the small bowel, but nothing was found. I have not seen anything in this collection of films to lead me to believe that that observation was incorrect. His appendix is visible and well filled, it appears to be normal. I do not believe the mass was due to an abscess of the appendix or anything of that sort. He has a very wide duodenal loop, but there are no changes in the mucosa of the duodenum and no evidence of block, and a wide loop, particularly in a patient with a high stomach, is of no real significance although one might consider more carefully tumor in the head of the pancreas. The films of the urinary tract show the kidney outlines to be normal, the location is normal, and there is nothing unusual in the appearance of the kidney pelvis.

DR. ADAMS: It seems to me we can best explain this confusing clinical picture by making a diagnosis of malignant lymphoma. An ulcerative lesion high in the small intestine could account for the hematemesis, especially if there is partial obstruction and, as we know, a lesion in the small intestine is often overlooked by the roentgenologist. The lower abdominal mass could well be enlarged lymph nodes, mesenteric or retroperitoneal. The relatively high polymorphonuclear count would also fit in with the diagnosis of lymphoma. And as far as I can see, there is nothing in the picture which might exclude such a diagnosis. If lymphoma involves the stomach, the gastric acidity is usually low rather than high. However, in this case, we do not suspect a lesion in the stomach. I do not know what degree of gastric acidity is common in cases of lymphoma involving that intestinal tract. Some less common form of tumor, such as leiomyoma, I suppose should be mentioned, but there is no evidence for or against it.

On second admission, the story of feeling fairly well except for occasional attacks of epigastric burning, relieved by milk and crackers, is especially characteristic of gastric or duodenal ulcer. One can conceive of its being consistent with an ulcerating lesion somewhat lower down. This and the high gastric acidity are the only bits of evidence which we have in favor of peptic ulcer. There is no report as to how the man was treated between his first and second admissions and I wonder if by any chance he was given radiation.

DR. TRACY B. MALLORY: I am sure he did not have radiation. He may have been on a gastric diet.

DR. ADAMS: "He was unable to sleep because

## DIFFERENTIAL DIAGNOSIS

DR. RICHARD SCHATZKI The patient was, so far as I remember, sent to the X-ray Department merely to exclude the possibility that there was anything wrong with the stomach or duodenum.

DR. MILES P. BAKER They evidently thought at the time that the emetine therapy had been a success, the fever was down.

DR. SCHATZKI I was surprised when I found this huge lobulated mass which was described in the record. It occupied the body of the stomach, like a bunch of big grapes. When you see such a mass in the stomach, particularly if it is lobulated, you like to see the stalk with which it is attached to the wall because that is the only possible way of differentiating a polypoid lobulated tumor and foreign material in the stomach. I was thinking of a case that had been discussed here recently in which I was not able to demonstrate such attachment. Because of the persistence of the shadow on several examinations I finally called it tumor, but it proved to be merely a blood clot. I therefore tried to demonstrate the attachment here and was not able to do so. In addition the mass moved within the stomach about 3 cm. up and down. Nevertheless, the appearance of the mass was much more characteristic of a lobulated tumor than it had been in the other case. I did not have much doubt about the case, but because of the preceding one I asked for a gastroscopy. Unfortunately the patient's condition did not permit this.

DR. BAKER Is this mass in a position consistent with the physical finding of a firm mass in the left upper abdomen?

DR. SCHATZKI The position is consistent, but I would not expect this particular type of tumor to be very firm.

DR. BAKER Does it appear definitely intrinsic?

DR. SCHATZKI Yes, a definitely lobulated mass within the stomach.

DR. BAKER This is the story then of a man who for four or five months prior to hospital admission had a mild day-and-night diarrhea, watery movements of the sort that one finds in individuals who have an irritative lesion of the small intestine, as ileitis. There has been no tendency to alternating constipation and diarrhea. Prior to entry he developed acute colicky pain localized chiefly in the right lower quadrant. It is similar to that seen with mild, partial intestinal obstruction. As we read on we find this to be a case of diarrhea with negative barium enema, without evidence of inflammatory colitis or malignancy in the colon. It was evidently hoped that emetine would prove a

specific therapy if the man had amebiasis, but, despite the subsidence of fever as the case progressed, it proved to be a false hope. Prior to the putting up of these x-ray films I thought of certain possibilities in diagnosis, but I can no longer believe that they are tenable. One of them in view of the positive bromsulfalein retention was the possibility that the man had portal cirrhosis with a primary carcinoma of the liver. The finding of intrinsic tumor in the stomach makes this unlikely. I thought possibly it was a tumor in the left lobe of the liver causing extrinsic pressure defect in the stomach.

I think that the bromsulfalein test here sticks out like a sore thumb because it indicates extensive intrahepatic disease. A marked dye retention of 35 per cent at the end of half an hour is a rare finding in metastatic malignancy in the liver. The negative Takata-Ara test is not consistent with any diffuse disease of the liver but is the rule with metastatic malignancy in the liver. Dr. Clark Heath reported positive Takata-Ara test in 60 per cent of cases of portal cirrhosis\*. Dr. Neil L. Crone says that in this hospital all the cases of obvious decompensated portal cirrhosis have a positive Takata-Ara test, but only 75 per cent of so-called compensated portal cirrhosis have a positive test. One finds generally that the Takata-Ara test findings do not tally well with other tests of liver function. The negative Takata-Ara test here is consistent then with cirrhosis of the liver, without ascites, and is to be expected if he has metastatic malignancy in the liver.

Secondly, I considered the possibility that this man had carcinoma of the body of the pancreas developing as an epigastric mass above the lesser curvature of the stomach and causing pressure defect with marked metastasis to the liver. Carcinoma of the pancreas sometimes begins with diarrhea. On the whole we have very little evidence that there is such a disease, to judge from the x-ray findings. I believe cancer of the pancreas can involve the transverse colon. I suppose it is conceivable that it involves the stomach wall too, but that must be a very rare finding. A third possibility is lymphoma, producing irritative symptoms in the small intestine. His symptoms began with gradual decrease in strength, with attacks of colicky pain consistent with mild intestinal obstruction. Evidence of liver involvement developed from the laboratory examinations and eventually a tumor of the stomach was demonstrated. Lymphoma may diffusely infiltrate the liver in such fashion as to account for the evidence by laboratory test of diffuse intrahepatic disease. Cer-

\*Heath, C. W. The Takata-Ara test in the diagnosis of liver disease. New Eng. J. Med. 211:107-108, 1934.

## CASE 25112

## PRESENTATION OF CASE

A fifty-year-old married Canadian carpenter was admitted complaining of lower abdominal cramps of ten days' duration.

The patient was entirely well until he noted the insidious onset of painless watery diarrhea five months prior to admission. This continued with a frequency of four to six movements per day, some occurring at night, without mucus, blood or pus. His appetite remained good and he had no nausea or distention. Twelve days before entry, without apparent precipitating cause, cramp-like lower abdominal pains began, recurred at intervals of a few minutes to three hours, day and night, and lasted until entry. They seemed to be somewhat aggravated by eating. The pain was of a spasmodic nature, "like something turning inside," not localized to a definite area. It began in the right lower quadrant, but during the first night moved into the epigastrium. During the last few days it had also involved the entire lower abdomen and the left flank. His diarrhea continued. There was no relief of pain after a bowel movement. He vomited only once, five days before admission, after taking "creamy" medicine ordered by his physician. A tender area developed just below the xiphoid in the midline. He had lost 15 pounds in weight during the last six months. He had not had chills or fever. No questionable food, water or milk had been ingested and no one with whom he was associated had a similar condition. His past and family histories were non-contributory.

Physical examination showed a dehydrated man having episodes of acute abdominal distress. Examination of the chest was negative. The blood pressure was 115 systolic, 65 diastolic. The abdomen was soft. There was a small tender area just beneath the xiphoid in the midline, apparently over the left lobe of the liver. There was no tenderness on percussion over the right costal margin. No organs or masses were palpable.

The temperature was 101°F, pulse 65, respirations 25.

The urine examination was negative. The blood showed a red-cell count of 3,700,000 with 70 per cent hemoglobin and a white-cell count of 12,200 with 78 per cent polymorphonuclears, 20 per cent lymphocytes, 2 per cent eosinophils. The red cells showed slight anisocytosis. The serum nonprotein nitrogen was 20 mg per cent, the chlorides 101 milliequivalents. A van den Bergh test was normal, indirect. A bromsulfalein test of liver function showed 35 per cent retention of the dye. A Takata-

Ara test was negative. Several blood cultures showed no growth. A stool examination was guaiac negative. A stool culture showed no pathogenic organisms. Typhoid and Paratyphoid A and B agglutination tests were negative. An undulant fever agglutination test was weakly positive in all dilutions from 1:40 to 1:1280.

A barium enema x-ray examination was negative.

On the third hospital day the patient's temperature had risen to 104°F. Tenderness in the epigastrium was more marked, and percussion over the right costal margin was quite painful. The pulse was only 80, despite the high temperature. The spleen was not palpable. There were no rose spots. A proctoscopic examination showed a slightly pale and edematous mucosa. There were no ulcers. An examination for amebae was negative. Two days later the liver remained tender, but the temperature was lower and the patient was symptomatically improved. On the seventh hospital day an x-ray of the chest showed a diaphragm unusually high on the right. The right lower lung field showed decreased radiance apparently due to pressure atelectasis. Emetine hydrochloride therapy had been started on the third hospital day and given daily. On the ninth hospital day the temperature had returned to normal. On the following day a stool examination was guaiac positive. A gastrointestinal x-ray series taken on the fourteenth hospital day showed a lobulated mass occupying the upper half of the stomach. However, a re-examination was requested to rule out foreign material. Three days later a fixed, firm mass was palpated in the left epigastrium. The liver was enlarged and nodular, extending 4 cm below the right costal margin. A repeat gastrointestinal x-ray series at this time showed a lobulated mass in the stomach.

Again it was not possible to demonstrate a definite attachment of this mass to the stomach wall. The mass seemed to lie slightly lower in position than on the previous examination. On the twenty-first hospital day the patient vomited yellow mucoid material which was guaiac negative. One day later he vomited 100 cc of reddish fluid which was guaiac positive. Jaundice was noted at this time and a van den Bergh test was diphasic with 7.35 mg per cent bilirubin. The liver continued to enlarge. On the twenty-third hospital day the upper border was at the fifth rib, the lower edge 8 cm below the costal margin in the right mid-clavicular line. The patient continued to vomit reddish-brown, guaiac positive material and the jaundice deepened. He rapidly failed and died on the thirty-second hospital day.

## A MEDICAL HISTORIAN LOOKS AT SOCIALIZED MEDICINE

It is not easy in these times for anyone even to try to investigate certain aspects of socialized medicine. The very fact that a physician makes an effort to collect data from the Soviet Union and other places puts him, in the minds of many of his colleagues, far to the left and even attaches to him a red tag. Because of this, great credit should be given to any individual who has the courage to investigate Soviet medical practices thoroughly, although the fact that his passport carries a Russian visa gives him, to some more narrow-minded individuals, a distinct stamp of disapproval. Whatever may be the individuals' feeling about the matter, one cannot ignore the fact that the socialization of medicine is already largely accomplished in certain countries and that steps in that

direction are discernible even in democratic countries such as ours. One hears so much against socialized medicine that it is rather refreshing to find a medical historian looking at the subject, as a historian should, from an impartial point of view. Unquestionably the world's leader in the history of medicine at the present time is Dr. Henry E. Sigerist, the head of the Johns Hopkins Institute of the History of Medicine. He, as is well known, has made a thorough study of the socialistic trends in medicine in the last few years, and the facts which he presents must be given great weight, if the problem is to be met fairly by American physicians.

Fortunately, due to the energy of the weekly news magazine *Time*, a summary of the views for socialized medicine, as brought out by Dr. Sigerist, is published in the issue of January 30, 1939. Briefly, the seven points made in his argument are

(1) State control of medicine is not a radical departure, for more than 60 per cent of all hospital beds in this country are owned and operated by governmental agencies. A large part of the care of patients with tuberculosis, blindness, leprosy and narcotic addiction falls under the direction of physicians paid by the United States Public Health Service.

(2) The opinion is expressed that to finance a system of state medicine in the United States would be neither difficult nor extravagant. A considerable portion of the money now spent in a haphazard and wasteful manner by the people might be saved if a scheme of care at least partly under government control was inaugurated. The indigent, under such a plan, would receive complete medical care without cost, low income groups would be financed through compulsory health insurance, while the higher income groups could take care of their health in any way that they pleased.

(3) It is pointed out that although the argument is often used that salaried doctors lose their incentive to do good work, physicians such as Koch, Pasteur, Gorgas, Reed and Welch were all salaried men. So are the workers in the Mayo Clinic and the Rockefeller Institute for Medical Research and about 15 per cent of the United States doctors working in institutional hospitals.

(4) Socialized medicine would limit the free choice of a physician, but it is pointed out that few have a free choice today. A considerable percentage of the population attend clinics and hospitals without knowing which doctor is to see them. There are also many private clinics operating in part in the same manner.

(5) It is pointed out that socialized medicine would not spoil the personal relation between a patient and a

tainly the fever, the anemia and the leukocytosis are consistent with such a diagnosis. Multiple areas of involvement of the bowel are rather characteristic of lymphoma and though there is no direct evidence of a lesion in the lower intestinal tract the symptoms certainly suggest one.

Is this primary adenocarcinoma of the stomach with metastasis to the liver? Were it such, I would expect the patient to have more definite stomach symptoms, with the accent on anorexia and active nausea rather than lower intestinal symptoms at the onset of the disease. It is an interesting combination of stomach mass and lower intestinal symptomatology. I think some such diffuse disease as lymphoma is the most tenable diagnosis.

DR. TRACY B. MALLORY: Dr. Schatzki, how would you feel about the possibility of the stomach tumor being lymphomatous?

DR. SCHATZKI: I do not think I have ever seen lymphoma produce such a lobulated polypoid type of lesion. If this is tumor it must have a comparatively small attachment and the main mass is polypoid. From my own experience it is very unlikely to be lymphoma. I would from the x-ray appearance clearly rule out lymphoma.

DR. MALLORY: How would you feel about it, Dr. Benedict?

DR. EDWARD B. BENEDICT: I did not see this patient and did not gastroscopically examine him, but I was wondering if he could have had multiple polypoid lesions of the stomach as well as of the colon.

DR. BAKER: The barium enema was negative.

DR. BENEDICT: I cannot make a diagnosis.

#### CLINICAL DIAGNOSIS

Carcinoma of the stomach with metastasis to liver

#### DR. BAKER'S DIAGNOSIS

Lymphoma of stomach, liver and small intestine.

#### ANATOMICAL DIAGNOSES

Polyposis of stomach with malignant degeneration

Metastatic carcinoma to the liver

Icterus

Bilateral healed apical tuberculosis

#### PATHOLOGICAL DISCUSSION

DR. MALLORY: This case is like the preceding one in that the clinical symptoms seem to point to the lower intestinal tract, but the findings are all in the upper intestinal tract. The stomach showed about five polypoid lesions of which one was frankly malignant, two frankly benign and two questionable. The liver was very extensively involved with metastases, weighed 4500 gm. and three quarters of that weight was, I am sure, due to metastatic carcinoma. It is quite true that we very rarely see evidence of liver insufficiency with metastatic cancer, but in this case it was present. There was a great deal of necrosis of liver cells around the tumor nodules apparently from pressure or perhaps from interference with the blood supply that may have had something to do with the clinical evidence of liver insufficiency.

A PHYSICIAN: Was the spleen enlarged?

DR. MALLORY: The spleen was normal. The lower intestinal tract was absolutely normal, nothing whatever was found to account for the diarrhea except the stomach and the liver involvement.

POSTPARTUM HEMORRHAGE DUE  
TO A PARTIALLY ADHERENT PLACENTA

Mrs. R. F., a thirty-two-year-old para III, at term, entered the hospital in active labor on November 20, 1937.

The family history was essentially negative, as was the patient's past history. Catamenia began at thirteen, were regular with a twenty-eight-day cycle and lasted four days without pain. Her two previous pregnancies had been normal and resulted in normal deliveries. Her last period was said to be December 25, 1936, making her due for delivery October 1, 1937, but it was assumed that her dates were confused. The present pregnancy had been normal throughout.

Physical examination at entry showed a well-developed and well-nourished woman. Her heart was not enlarged, there were no murmurs. Her lungs were clear and resonant, there were no rales. The blood pressure was 114 systolic, 64 diastolic. The fundus was three fingers below the ensiform, with the vertex in the LOA position and engaged. The fetal heart was heard at the rate of 140 in the left lower quadrant. Her pelvic measurements were normal.

Her labor was short and active, without benefit of any medication. She was delivered normally of a 7 pound, 12 ounce, female child at the end of four hours. One ampule of posterior pituitary extract was administered at the end of the second stage of labor. At this time the pulse rate was 104. The fundus did not react well, the placenta did not separate entirely, and she bled steadily and moderately. She was therefore etherized, and a manual extraction of the placenta was performed without difficulty one hour after the birth of the baby. Following this, the patient went into a state of shock with a pulse of 144. Intravenous glucose was attempted, but the veins were collapsed. A vein was cut down upon, and 2000 cc. of 5 per cent glucose was administered. At the end of this time her blood pressure was 100 systolic, 44 diastolic. The uterus seemed to be in good condition, and it was believed that the patient was out of danger. Additional pituitary ex-

tract and an ampule of Ergotrate had been given before and after the extraction of the placenta.

Within an hour the patient had again lapsed into shock, with a blood pressure of 80 systolic, 56 diastolic, and a pulse at the rate of 168, which was weak and irregular. The fundus was soft and enlarged, and the patient bleeding. Accordingly the uterus and vagina were tightly packed. This effectively controlled the hemorrhage. Another intravenous injection of glucose was given. The pulse rate was 190 and almost impossible to obtain. The blood pressure was 60 systolic, 50 diastolic, and caffeine and Coramine were given. As suitable donors had been procured, a citrate transfusion of 600 cc. of blood was given. The pulse came down to 120 and was regular but thready. An hour after the first transfusion 500 cc. of additional blood was administered. The pulse rate was then 114, the blood pressure 110 systolic, 70 diastolic, and although she was weak and pale, she was out of shock, with a pulse of fair quality and no bleeding.

For the next twenty-four hours, she had a pulse rate of about 140, and the blood pressure was 130 systolic, 60 diastolic. During this time she received 2000 cc. of 10 per cent glucose in distilled water, it was allowed to run in over a period of eight hours. The uterine pack was removed at the end of this time. Her fundus remained firm, and there was no more bleeding. She ran a septic course for a week and was discharged on the twenty-second day. Her red-blood-cell count was 3,750,000 and the hemoglobin 75 per cent on the seventeenth day.

*Comment.* This case of postpartum hemorrhage was due to a partially adherent placenta and emphasizes the need of carefully watching every fundus after the placenta has been delivered, especially one in which postpartum hemorrhage has occurred. It is doubtful whether this fundus was carefully watched after the placenta was removed. It is also possible that the packing of the uterus at the beginning might have prevented the secondary hemorrhage. Intravenous pituitary extract was not used, it might have been valuable.

CHAPTER 112, SECTION 8 OF THE GENERAL  
LAWS OF MASSACHUSETTS

At the request of a fellow of the Massachusetts Medical Society we are reprinting Chapter 112, Section 8, of the General Laws of Massachusetts.

No person shall enter upon, or continue in, the practice of medicine within the commonwealth until he has presented to the clerk of the town where he has, or intends to have, an office or his usual place of business, his certificate of registration as a physician in the commonwealth, or, if it is lost, a certified state

\*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are welcomed and will be discussed by members of the section.

physician The fact that a doctor is a member of an organized group does not spoil this relation What really spoils it is that the doctor has to charge a fee and the patient has to pay the bill Once the money question is removed, the relation between physician and patient becomes purely human

(6) Socialized medicine need not lower the standard of medical care There is no reason, as a matter of fact, why care should not be better under group practice, such as is exemplified by the outpatient departments of ordinary hospitals

(7) Finally, there is the question of whether government control would bring politics into medicine It should be pointed out that the United States Public Health Service, one of the most efficient in the world, has always been free from politics It seems reasonable to assume, moreover, that any matter dealing so intimately with the public as the question of their health would develop behind it a strong enough public opinion to overcome meddling by politicians

These are the arguments that are used for socialized medicine Whether such a scheme could actually be put into practice, is another question, of which Dr Sigerist is not unmindful In order to study the condition historically he will ask his students to investigate certain parts of the State of Maryland with the idea of outlining a plan to put into practice socialized medicine, guaranteeing to give to every individual the best possible medical care By methods such as this a question which is vexing the whole medical world may be solved At least if we do not look at the problem from all sides, we are sure to let our judgment be swayed by emotions rather than by our intellect *Time* has done a distinct service to the medical profession in presenting Dr Sigerist's view in a clear-cut and interesting manner It is hoped that its editors, in turn, will interview an exponent of the opposite theories and present the arguments against socialized medicine in a manner of equal impartiality

## THE ADAPTABILITY OF THE HUMAN MIND

In the early years of the depression a nationally known labor leader issued a statement to the effect that if economic security was not speedily restored, chaos would result, men could not stand the pressure of opposing circumstances, their minds would

give way and they would go mad Men's minds did, of course, give way in those days, and men did go mad, just as they have, and will, in every known year and under all conceivable circumstances The mass of men, however, shifted their pace to suit the rate of travel and continued on their way

We adapted ourselves in 1914 and 1915, and particularly in 1917, to the idea of a world war, and did it with surprising alacrity and thoroughness It is useless to go back through history to see how often and under what conditions man has adapted himself to changing environmental influences, history, in our minds, is a dead record of things that cannot happen again

The prewar era, it is true, represented a rather long and rather static period Capitalism and the upper middle classes were firmly entrenched in a pious position of not positively unfriendly domination Labor was allowed a full dinner pail, the country had a fairly good five-cent cigar, and there was nothing to go mad about unless the wrong team won the pennant

What a change was wrought in 1914! First came a world war with a pandemic of disease, then a minor depression, a period of unprecedented prosperity,—and this was the hardest on men's minds,—a great depression, several pseudo recoveries, floods, hurricanes and tidal waves in New England,—of all places,—a shift to the left in our country's politics, again the tread of armed feet over Europe, the British lion with his tail between his legs, a definitely threatened yellow dominancy, and War Admiral again beaten by Sea Biscuit

Dare we predict that if the worst happens,—if socialized medicine strikes at the very tap root of family practice,—if white dominancy and the civilization that started with the Renaissance go down to glory in a blaze of gunfire, when the smoke clears, those of us who are left will be found with our noses pressed against the window-pane, trying to get the latest baseball scores, or lined up before the totalizer to find our winnings when Plum Pudding beats Humble Pie by a length?

'heart attacks or cardiovascular emergencies  
Instructor Edward F Bland Alexander A.  
Levi, *Chairman*

## SUFFOLK

Thursday, March 23, at 4 30 p m., in John Ware Hall,  
Boston Medical Library, 8 Fenway, Boston Sub-  
ject—Cardiovascular Emergencies Instructor  
Paul D White. Reginald Fitz, *Chairman*

case, and derogated *id omne genus* in the epitaph's last  
caustic line.

Here is the inscription

## RUTH SPRAGUE

daughter of Gibson  
& Elizabeth Sprague,  
died Jan 11, 1846, aged  
9 years 4 mo's & 3 days

She was stolen from the grave  
by Roderick R. Clow & dissected  
at Dr P M. Armstrong's office  
in Hoosick N Y from which place  
her mutilated remains were  
obtained & deposited here.

Her body dissected by fiendish Men  
Her bones anatomised,  
Her soul we trust has risen to God,  
Where few Physicians rise.

We hope that there is less truth than poetry in the last line.

Far from these diggings, in Edinburgh, the body-  
snatching industry enriched the language by contributing  
the verb to burke. This word is used more across the  
water than here. In the House of Commons, the Minis-  
ters are often accused of 'burking a bill' in some com-  
mittee.

The following *cause celebre* produced the verb. A  
friendless old army pensioner died in a cheap lodging  
house in Edinburgh. The lodging-house keeper, William  
Hare, sold the unclaimed body without difficulty to Dr  
Robert Knox for 7 pounds, 10 shillings.

This profitable transaction furnished the idea for a new  
cottage industry. William Burke became Hare's accom-  
plice in the hospitable practice of inveigling a series of  
obscure, friendless travelers to the lodging house, where  
they made them drunk. Then they suffocated them  
tenderly, so that there would be no marks of violence.  
The same Dr Knox bought all the proffered bodies at  
factory prices, varying from 8 to 14 pounds. After sixteen  
bodies were delivered to science, the police became sus-  
picious and effective. Hare turned King's evidence, and  
Burke was hanged at Edinburgh, on January 28, 1829.  
An excellent account of the case is given in *Burke and  
Hare* (Edinburgh and London: William Hodge and Com-  
pany, Ltd, 1921).

Soon thereafter, the word *burke* was used to indicate  
any quiet and decorous smotherings, where the *corpus  
delicti* disappeared without trace (*spurio versenkt*).  
Dickens used the word in *Pickwick Papers*.

You don't mean to say he was burked, Sam?

Let us hope that all bad medical bills will be burked in  
committee.

EDWARD F TIMMINS M.D.

527 Broadway,  
South Boston

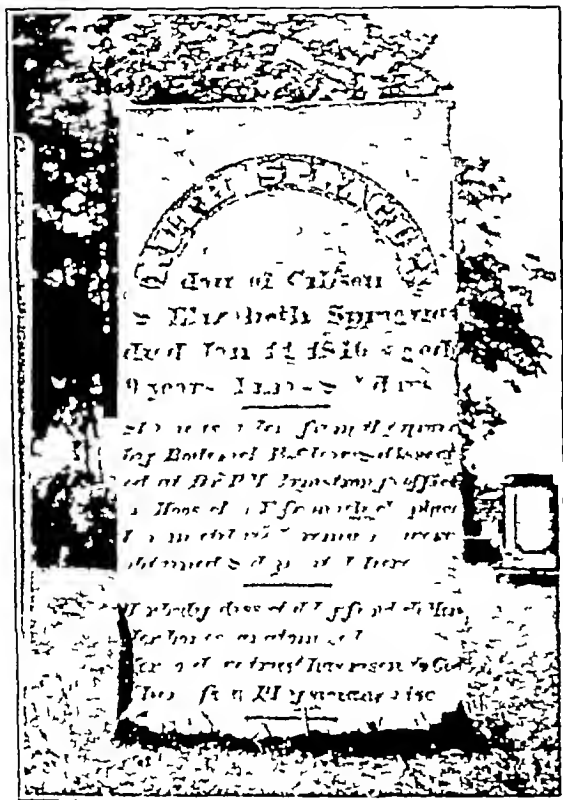

## DR. WILLIAM GAMAGE

*To the Editor* The following account of a remarkable  
man is from S F Batchelder's *Bits of Harvard History*  
(Cambridge: Harvard University Press, 1924). Under the  
title of *Harvard Hospital Surgeons of 1775* we find the  
following: Dr William Gamage of the class of 1767 was  
the regular Cambridge practitioner. He was an allopath  
of the allopaths.

## CORRESPONDENCE

## BODY-SNATCHING

*To the Editor* In Hoosick Falls, N Y, there is a his-  
toric gravestone with a censorious inscription which  
should interest the readers of Dr Waite's article on the  
body snatching activities of our old time anatomists. Be-

cause of the weathering of the stone, the inscription is less  
distinct than it was when I first saw it, ten years ago.  
Nevertheless, the cold marble has distinctly reprobated  
the overzealous Dr P M. Armstrong for more than a  
hundred and twenty years.

In the case of the Ipswich exhumations, the parish  
meeting appointed a day for the solemn reinterment of  
the eight empty coffins in some conspicuous part of the  
graveyard, and voted that a monument be erected over  
them by subscription with the names of the deceased  
whose bodies were stolen inscribed thereon, to perpetuate  
the memory of the horrid deed. But for lack of funds  
no such monument was erected. The outraged parents  
attended to the vindictive publicity in the Hoosick Falls

ment issued by the board, setting forth all the material facts in the original certificate, and a fee of twenty five cents. Thereupon the clerk shall record the name of the owner of said certificate or certified statement, together with the date of record, upon blanks approved by the board, said blanks to be so arranged that a duplicate carbon copy shall be made at the time of the original record. He shall keep the original as a part of his official records and it shall be open to public inspection. He shall, within twenty four hours after such recording, forward the duplicate to the board. Whoever practices or attempts to practice medicine without complying with this section, or whoever submits to a town clerk a false or fraudulent certificate or certified statement, shall be punished by a fine of not less than five nor more than one hundred dollars, and any town clerk who refuses or neglects to comply with this section shall be punished by a fine of not less than five nor more than ten dollars.

## LEGISLATIVE NOTES

### MASSACHUSETTS MEDICAL SOCIETY BALLOT OF MARCH 2, 1939

COUNTED THROUGH MARCH 13 MORNING MAIL

TABLE 1 *Vote on Annual Registration by District Medical Societies*

DISTRICT	FAVOR	OPPOSE	BLANK

## MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning March 20

### BARNSTABLE

Sunday, March 26, at 4 00 p m., at the Cape Cod Hospital, Hyannis. Subject—Gonorrhea. Modern treatment of gonorrhea. Instructor Samuel N Vose. Donald E Higgins, *Chairman*

### BERKSHIRE

Thursday, March 23, at 4 30 p m., at the House of Mercy Hospital, Pittsfield. Subject—Sepsis. Instructor Joseph W O Connor. Melvin H. Walker, Jr, *Chairman*

### BRISTOL NORTH

Thursday, March 23, at 4 00 p m., at the Morton Hospital, Taunton. Subject—Syphilis. Latent syphilis—diagnosis and treatment. Instructor C. Guy Lane. Lester E Butler, *Chairman*

### BRISTOL SOUTH (Fall River Section)

Tuesday, March 21, at 4 00 p m., at the Union Hospital, Fall River. Subject—Heart Disease. The treatment of 'heart attacks' or 'cardiovascular emergencies'. Instructor Ashton Graybiel. Howard P Sawyer, *Chairman*

### FRANKLIN

Wednesday, March 22, at 8 00 p m., at the Franklin County Public Hospital, Greenfield. Subject—Whooping Cough. The present status of vaccine therapy both as prophylactic and therapeutic measure, the early diagnosis by laboratory procedures, and the treatment of complications. Instructor Edwin H Place. Halbert G Stetson, *Chairman*

### HAMPDEN

Thursday, March 23, at 4 00 p m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8 00 p m., in the Outpatient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. Subject—Gonorrhea. Modern treatment of gonorrhea. Instructor Oscar F Cox, Jr. George L. Schadt, *Chairman*

### MIDDLESEX EAST

Tuesday, March 21, at 4 00 p m., at the Melrose Hospital (Colby Hall), Melrose. Subject—Anemia. Modern methods in diagnosis and treatment of blood dyscrasias. Instructor Clark W Heath. Walter H Flanders, *Chairman*

### MIDDLESEX NORTH

Thursday, March 23, at 4 30 p m., at St. John's Hospital, Lowell. Subject—Bright's Disease and Hypertension. Evaluation of new therapy diagnosis. Instructor W Richard Ohler. William S Lawler, *Chairman*

### MIDDLESEX SOUTH

Tuesday, March 21, at 5 00 p m., at the Cambridge Hospital, 330 Mt. Auburn Street, Cambridge. Subject—Heart Disease. The treatment of

## NORFOLK DISTRICT MEDICAL SOCIETY

The next meeting of the Norfolk District Medical Society will be held in the Children's Pavilion of the New England Hospital for Women and Children, Dimock Street, Roxbury, on Tuesday evening, March 28, at 8 30 Tel GAR 0912

## PROGRAM

- Early Treatment of Club Feet. Dr Miriam Katzeff  
Case Study of Complete Transposition of the Great Vessels. Dr Bianca Lia.  
Demonstration of Congenital Hearts from the Obstetric Service. Dr Olga Leary  
Presentation of a Urological Case. Dr Susannah Friedman  
A Ten Year Study of Cesarean Section. Dr Marjorie Woodman

FRANK S CRUICKSHANK, M.D., *Secretary*

## NEW ENGLAND HEART ASSOCIATION

The next meeting of the New England Heart Association will be held at the Beth Israel Hospital on Monday evening, March 27, at 8 15

## PROGRAM

- The Significance of Variations in the Anatomy of the Coronary Arteries. Dr Monroe J Schlesinger  
The Circulatory Effects of Benzedrine and Paredrine and Their Clinical Significance. Dr Mark Altschule.  
The Incidence of Normal Cardiac Findings Following Acute Rheumatic Fever. Dr Morton G Brown  
The Significance of Changes in Blood Volume in Congestive Failure during Stages of Development and Recovery. Dr John Waller  
Relation of Arterial Hypertension to Coronary Arteriosclerosis and to Congestive Failure. Dr David Davis  
The Rate of Interchange of Substances between Plasma and Edematous Deposits. Dr Dorothy Rourke Giligan.  
A Study of Marked Arteriosclerosis in Patients with and without Angina Pectoris. Dr Herrman L Blumgart.  
Interested physicians and medical students are cordially invited to attend

EDWARD F BLAND, M.D., *Secretary*

## TUFTS COLLEGE MEDICAL SCHOOL ALUMNI ASSOCIATION

The annual meeting and dinner of the Tufts College Medical School Alumni Association will be held Wednesday evening, March 29, at the Hotel Somerset, Boston.

Changes in the medical school and progress of the medical school campaign will be discussed by President Leon ard Carmichael

ALONZO K. PINE, M.D., *President*

## CAMBRIDGE HOSPITAL

The regular clinicopathological meeting of the staff of the Cambridge Hospital will be held at the hospital, 330 Mt. Auburn Street, Cambridge, on Tuesday, March 21, at 8 30 p m.

Interesting pathological cases will be discussed

All members of the medical staff are cordially invited.

STEPHEN M BIDDLE, M.D., *Secretary*

Batchelder quotes from the late Dr. A. P. Peabody's account of Gamage in *Harvard Graduates Whom I Have Known* (Boston: Houghton Mifflin Co., 1890), after telling us that Dr. Peabody, in his youth, knew the old gentleman. "His lavish over-medication," says Peabody, "gained for him unbounded popularity with the many who used a quantitative standard in estimating a physician's skill, and left traditions transcending easy belief in the succeeding generation."

"This style of treatment," Batchelder adds, was encouraged by the custom in vogue whereby a doctor charged, not for his visits, but for the medicine he supplied. Gamages bill to The Colony of Massachusetts Bay—'From the 19th of April to 17th of August, 1775—is still preserved, and is of unique interest as the earliest known document of its kind in the medical history of the Revolution. According to custom, he makes no charge for 'Attending Upon The Sick And Wounded In The Provincial Army, And Upon The Wounded Regulars,' but for 'Medicine Advanced For The Wounded Regulars, In April, 1775' sets down items totalling 15s 7d, and for 'Medicine Advanced For The Provincial Army In April And May, 1775' makes a footing of 14s 8d. The 17th of August probably marks the date when he ceased to prescribe as a semi-independent civilian, and became a regular hospital mate, as noted hereafter. He did not follow the army when it left Cambridge, but continued his undisputed sway as the medical autocrat of the town until his death in 1821."

"Gamage," continues Batchelder, was a character worthy of the pen of Cervantes or Moliere and left behind him a deeper impression than any other physician of his time. In his last years his personality was indelibly stamped upon the childish memories of both the Holmes brothers. Oliver Wendell Holmes delineates him thus: Grim, taciturn, rough in aspect, his visits to the household were the nightmares of the nursery. He would look at the tongue, feel the pulse, and shake from one of his phials a horrible mound of powdered ipecac, or a revolting heap of rhubarb—good stirring remedies that meant business, but left a flavor behind them which embittered the recollections of childhood. This was the kind of practice many patients preferred in those days, they liked to know they had taken something energetic and active, of which fact they were soon satisfied after one of Dr. Gamage's prescriptions.

We are told that John Holmes 'puts his reminiscences into the mouth of his 'Cambridge Robinson Crusoe' Oh, Dr. Gamage! He and his old yellow mare's about as tough as anything in Cambridge. What a pair they be! She is rhubarb color and his old surtout is just the color of ipecac. Oh, don't he give a feller the stuff! It's just like letting a cat down into a feller's stomach and pulling her out by the tail. I do declare, Captain, fur off as I am, it gives me a sort of a twist inside when I think of it.' Batchelder adds that John Holmes's imitation of Gamage making a professional call was something never to be forgotten by the few who were privileged to behold it.

Batchelder states that the late Dr. H. P. Walcott supplied him with the following example of the doctor's methods: 'Miss Eliza Ware, who lived as a child in the old Waterhouse cottage, remembered Gamage well. He used to wear an enormous waistcoat reaching almost to his knees, with some twenty small pockets, each containing a different drug in powdered form. On one occasion she had a fever. Dr. Gamage was summoned, and after a brief examination growled, 'Better have a little jalap.' He fumbled in a certain pocket, brought out a pinch of jalap, called for a glass of water, dropped in the nauseous purge,

stirred it with an abominably dirty forefinger, and ordered: 'Now, little girl, drink this!' It is to be hoped that when the good doctor had occasion to renew his waistcoat charges he put them all in the right pockets!

W. M. PEARCE COUES, M.D.

12 Monmouth Court,  
Brookline.

## NOTICES

### MEDICAL CLINIC AT THE PETER BENT BRIGHAM HOSPITAL

At 3 30 p. m. on Thursday, March 23, in the amphitheater of the Peter Bent Brigham Hospital, Dr. James P. O'Hare will give a medical clinic. Practitioners and medical students are cordially invited to attend.

### BOSTON DOCTORS' SYMPHONY ORCHESTRA

Nicolas Slonimsky

Rehearsals of the newly organized Boston Doctors' Symphony Orchestra, conducted by Nicolas Slonimsky, are held every Thursday evening at 7 30 at Hampton Court Hotel, 1223 Beacon Street, Brookline.

Membership is still open. All physicians, dentists and medical and dental students who are interested should communicate with Dr. Julius Loman, Pelham Hall Hotel, Brookline (BEA 2430).

### BOSTON MEDICAL HISTORY CLUB

A meeting of the Boston Medical History Club will be held at the Boston Medical Library, 8 Fenway, Boston, on Monday evening, March 20, at 8 15.

Dr. A. Warren Stearns will talk on 'Something Wrong with the Guts.'

Members of the medical profession and other interested persons are cordially invited to attend.

PAUL D. WHITE, M.D., *President*  
BENJAMIN SPECTOR, M.D., *Secretary*

### CARNEY HOSPITAL

The monthly clinical meeting and luncheon of the Carney Hospital will be held in Andrew Carney Assembly Hall on Monday, March 20, at 11 30 a. m.

#### PROGRAM

Conservative Versus Radical Treatment of Acute Biliary Disease Dr. Laurence J. Louis

Sulfapyridine (M & B 693) in Pneumonia Dr. John F. Casey

Unrecognized Pathological Conditions in Muscles. Dr. Matthew V. Norton

Some Aspects of Bleeding in Pregnancy Dr. Cornelius T. O'Connor

Physicians and medical students are cordially invited to attend.

ROY J. HEFFERNAN, M.D., *Secretary*

## NORFOLK DISTRICT MEDICAL SOCIETY

The next meeting of the Norfolk District Medical Society will be held in the Children's Pavilion of the New England Hospital for Women and Children, Dimock Street, Roxbury, on Tuesday evening, March 28, at 8 30 Tel. GAR 0912.

## PROGRAM

- Early Treatment of Club Feet. Dr Miriam Katzeff  
Case Study of Complete Transposition of the Great Vessels. Dr Bianca Lia.  
Demonstration of Congenital Hearts from the Obstetric Service. Dr Olga Leary  
Presentation of a Urological Case. Dr Susannah Friedman.  
A Ten-Year Study of Cesarean Section. Dr Marjorie Woodman

FRANK S. CRUICKSHANK, M.D., *Secretary*

## NEW ENGLAND HEART ASSOCIATION

The next meeting of the New England Heart Association will be held at the Beth Israel Hospital on Monday evening, March 27, at 8 15

## PROGRAM

- The Significance of Variations in the Anatomy of the Coronary Arteries. Dr Monroe J. Schlesinger  
The Circulatory Effects of Benzadrine and Paredrine and Their Clinical Significance. Dr Mark Altschule.  
The Incidence of Normal Cardiac Findings Following Acute Rheumatic Fever. Dr Morton G. Brown  
The Significance of Changes in Blood Volume in Congestive Failure during Stages of Development and Recovery. Dr John Waller  
Relation of Arterial Hypertension to Coronary Arteriosclerosis and to Congestive Failure. Dr David Davis  
The Rate of Interchange of Substances between Plasma and Edematous Deposits. Dr Dorothy Rourke Giligan.  
A Study of Marked Arteriosclerosis in Patients with and without Angina Pectoris. Dr Herrman L. Blumgart.

Interested physicians and medical students are cordially invited to attend.

EDWARD F. BLAND, M.D., *Secretary*

## TUFTS COLLEGE MEDICAL SCHOOL ALUMNI ASSOCIATION

The annual meeting and dinner of the Tufts College Medical School Alumni Association will be held Wednesday evening, March 29, at the Hotel Somerset, Boston.

Changes in the medical school and progress of the medical school campaign will be discussed by President Leonard Carmichael.

ALONZO K. PAINE, M.D., *President*

## CAMBRIDGE HOSPITAL

The regular clinicopathological meeting of the staff of the Cambridge Hospital will be held at the hospital 320 Mt. Auburn Street, Cambridge, on Tuesday, March 21, at 8 30 p. m.

Interesting pathological cases will be discussed.

All members of the medical staff are cordially invited

Batchelder quotes from the late Dr A P Peabody's account of Gamage in *Harvard Graduates Whom I Have Known* (Boston: Houghton Mifflin Co, 1890), after telling us that Dr Peabody, in his youth, knew the old gentleman "His lavish over medication," says Peabody, "gained for him unbounded popularity with the many who used a quantitative standard in estimating a physician's skill, and left traditions transcending easy belief in the succeeding generation."

"This style of treatment," Batchelder adds, was encouraged by the custom in vogue whereby a doctor charged, not for his visits, but for the medicine he supplied. Gamage's bill to The Colony of Massachusetts Bay—'From the 19th of April to 17th of August, 1775—is still preserved, and is of unique interest as the earliest known document of its kind in the medical history of the Revolution. According to custom, he makes no charge for 'Attending Upon The Sick And Wounded In The Provincial Army, And Upon The Wounded Regulars,' but for 'Medicine Advanced For The Wounded Regulars, In April, 1775' sets down items totalling 15s 7d, and for 'Medicine Advanced For The Provincial Army In April And May, 1775' makes a footing of 14s 8d. The 17th of August probably marks the date when he ceased to prescribe as a semi-independent civilian, and became a regular hospital mate, as noted hereafter. He did not follow the army when it left Cambridge, but continued his undisputed sway as the medical autocrat of the town until his death in 1821."

"Gamage," continues Batchelder, was a character worthy of the pen of Cervantes or Moliere and left behind him a deeper impression than any other physician of his time. In his last years his personality was indelibly stamped upon the childish memories of both the Holmes brothers. Oliver Wendell Holmes delineates him thus: Grim, taciturn, rough in aspect, his visits to the household were the nightmares of the nursery. He would look at the tongue, feel the pulse, and shake from one of his phials a horrible mound of powdered ipecac, or a revolting heap of rhubarb—good stirring remedies that meant business, but left a flavor behind them which embittered the recollections of childhood. This was the kind of practice many patients preferred in those days, they liked to know they had taken something energetic and active, of which fact they were soon satisfied after one of Dr Gamage's prescriptions."

We are told that John Holmes puts his reminiscences into the mouth of his 'Cambridge Robinson Crusoe'

Oh, Dr Gamage! He and his old yellow mare's about as tough as anything in Cambridge. What a pair they be! She is rhubarb color and his old surtout is just the color of ipecac. Oh, don't he give a feller the stuff! It's just like letting a cat down into a feller's stomach and pulling her out by the tail. I do declare, Captain, fur off as I am, it gives me a sort of a twist inside when I think of it." Batchelder adds that John Holmes's imitation of Gamage making a professional call was something never to be forgotten by the few who were privileged to behold it.

Batchelder states that the late Dr H P Walcott supplied him with the following example of the doctor's methods: 'Miss Eliza Ware, who lived as a child in the old Waterhouse cottage, remembered Gamage well. He used to wear an enormous waistcoat reaching almost to his knees, with some twenty small pockets, each containing a different drug in powdered form. On one occasion she had a fever. Dr Gamage was summoned, and after a brief examination growled, 'Better have a little jalap.' He fumbled in a certain pocket, brought out a pinch of jalap, called for a glass of water, dropped in the nauseous purge,

stirred it with an abominably dirty forefinger, and ordered, 'Now, little girl, drink this!'" It is to be hoped that when the good doctor had occasion to renew his waistcoat charges he put them all in the right pockets!

## NOTICES

### MEDICAL CLINIC AT THE PETER BENT BRIGHAM HOSPITAL

At 3 30 p m on Thursday, March 23, in the amphitheater of the Peter Bent Brigham Hospital, Dr James P O'Hare will give a medical clinic. Practitioners and medical students are cordially invited to attend.

### BOSTON DOCTORS' SYMPHONY ORCHESTRA

Nicolas Slonimsky

Rehearsals of the newly organized Boston Doctors' Symphony Orchestra, conducted by Nicolas Slonimsky, are held every Thursday evening at 7 30 at Hampton Court Hotel, 1223 Beacon Street, Brookline.

Membership is still open. All physicians, dentists and medical and dental students who are interested should communicate with Dr Julius Loman, Pelham Hall Hotel, Brookline (BEA 2430).

### BOSTON MEDICAL HISTORY CLUB

A meeting of the Boston Medical History Club will be held at the Boston Medical Library, 8 Fenway, Boston, on Monday evening, March 20, at 8 15.

Dr A Warren Stearns will talk on "Something Wrong with the Guts."

Members of the medical profession and other interested persons are cordially invited to attend.

PAUL D WHITE, M.D, *President*  
BENJAMIN SPECTOR, M.D, *Secretary*

### CARNEY HOSPITAL

The monthly clinical meeting and luncheon of the Carney Hospital will be held in Andrew Carney Assembly Hall on Monday, March 20, at 11 30 a m.

#### PROGRAM

Conservative Versus Radical Treatment of Acute Biliary Disease. Dr Laurence J Louis

Sulfapyridine (M & B 693) in Pneumonia. Dr John F Casey

Unrecognized Pathological Conditions in Muscles. Dr Matthew V Norton

Some Aspects of Bleeding in Pregnancy. Dr Cornelius T O'Connor

Physicians and medical students are cordially invited to attend.

ROY J HEFFERNAN, M.D, *Secretary*

## NORFOLK DISTRICT MEDICAL SOCIETY

The next meeting of the Norfolk District Medical Society will be held in the Children's Pavilion of the New England Hospital for Women and Children, Dimock Street, Roxbury, on Tuesday evening, March 28, at 8 30 Tel GAR 0912

## PROGRAM

- Early Treatment of Club Feet Dr Miriam Katzeff  
Case Study of Complete Transposition of the Great Vessels Dr Bianca Lia.  
Demonstration of Congenital Hearts from the Obstetric Service Dr Olga Leary  
Presentation of a Urological Case. Dr Susannah Friedman  
A Ten Year Study of Cesarean Section Dr Marjorie Woodman

FRANK S CRUICKSHANK, M.D., *Secretary*

## NEW ENGLAND HEART ASSOCIATION

The next meeting of the New England Heart Association will be held at the Beth Israel Hospital on Monday evening, March 27, at 8 15

## PROGRAM

- The Significance of Variations in the Anatomy of the Coronary Arteries Dr Monroe J Schlesinger  
The Circulatory Effects of Benzedrine and Paredrine and Their Clinical Significance. Dr Mark Altshuler.  
The Incidence of Normal Cardiac Findings Following Acute Rheumatic Fever Dr Morton G Brown  
The Significance of Changes in Blood Volume in Congestive Failure during Stages of Development and Recovery Dr John Waller  
Relation of Arterial Hypertension to Coronary Arteriosclerosis and to Congestive Failure. Dr David Davis  
The Rate of Interchange of Substances between Plasma and Edematous Deposits Dr Dorothy Rourke Giligan.  
A Study of Marked Arteriosclerosis in Patients with and without Angina Pectoris Dr Herrman L. Blumgart.  
Interested physicians and medical students are cordially invited to attend.

EDWARD F BLAND, M.D., *Secretary*

## TUFTS COLLEGE MEDICAL SCHOOL ALUMNI ASSOCIATION

The annual meeting and dinner of the Tufts College Medical School Alumni Association will be held Wednesday evening, March 29, at the Hotel Somerset, Boston.

Changes in the medical school and progress of the medical school campaign will be discussed by President Leonard Carmichael

ALONZO K. PAINE, M.D., *President*

## CAMBRIDGE HOSPITAL

The regular clinicopathological meeting of the staff of the Cambridge Hospital will be held at the hospital, 330 Mt. Auburn Street, Cambridge, on Tuesday, March 21, at 8.30 p m.

Interesting pathological cases will be discussed.

All members of the medical staff are cordially invited

STEPHEN M BIDDLE, M.D., *Secretary*

## BOOK REVIEWS

*Mental Conflicts and Personality* Mandel Sherman. 319 pp New York, London and Toronto Longmans, Green & Co, 1938 \$2 25

Psychiatry is coming to an increasing realization that conflict and anxiety are at the center of all types of mental disturbances and that their dynamic and descriptive evaluation furnishes valuable hints for psychotherapeutic adjustment. This realization has been largely the result of the interpenetration of psychoanalytic concepts into

psychiatry, for it is psychoanalysis which has emphasized that the basis of the neuroses is a conflict between instinctual drives and the defenses erected against them.

The various chapters of this volume discuss the genesis and nature of conflicts—cultural, social, inferiority and sexual—and the interrelations of these to neuroses and antisocial behavior.

While mental conflicts, as a rule, originate in early life, it is doubtful, however, if the child's conflicts are so few and simple as the author claims, as analyses of children have shown that they manifest very complicated reactions toward the family environment. The author justly criticizes the erroneous idea of congenital homosexuality and points out, as has been so frequently observed, that the difference between the normal and the homosexual individual is quantitative rather than qualitative.

Since the volume is essentially psychoanalytic, it appears to the reviewer that the references to the work of Freud are not sufficiently numerous. The most important chapters for the physician are those on the conflicts and the neuroses, and the conflict basis of antisocial behavior. There are detailed discussions on how the neurotic individual unconsciously maintains his symptoms in order to solve his conflicts, that is, that he unconsciously prefers neurotic misery to actual misery as the lesser of two evils and, by so doing, evades the real problems.

The volume is most welcome as an excellent summary of the present status of the psychology of human conflicts.

*Plastic Surgery* Arthur J. Barsky 355 pp Philadelphia and London W. B. Saunders Co, 1938 \$5 75

The author has attempted to present a review of clinical procedures, practiced daily in modern plastic surgery. The method of choice in any group of procedures is generally made clear. Although it should be noted that, in a field as relatively new as this, there is as yet no standardization of methods, hence, methods of choice are always highly personal.

The multiplicity of illustrations and the generally clear and reasonable statement of facts make this book very satisfactory. The material is up to date, and there is a pleasing discretion in the lack of space afforded new procedures which are as yet experimental.

The principles and fundamental theories underlying transplantations are well outlined early in the book. They are clearly presented and an ample bibliography is supplied, just as it is later at the end of each chapter on special topics. The sections on the orbit and nose are particularly good. Similarly it is welcome to find the neck treated in a separate section, since its problems are at times unique.

In conclusion it may be stated that this compact little volume will well repay perusal by anyone interested in the subject of modern esthetic reconstructive surgery.

*Les Ondes Électriques Courtes en Biologie* E. Schliephake. 96 pp Paris Gauthier-Villars, 1938 30 Fr fr

This concise little text presents in a very lucid style the basic principles of short-wave diathermy and its biologic effects. There is included in the volume a considerable amount of the author's original work. He has, furthermore, presented the dynamics of the electrophysics involved in each system and has correlated these findings with their effects on living cells. The work appears to be truly scientific in scope and is a welcome advance in the somewhat confusing field of physical therapy of today.

NUMBER 12

## AMERICAN MEDICINE AND THE NATIONAL HEALTH PROGRAM\*

MORRIS FISHBEIN, M.D.†

CHICAGO

I AM quite convinced that there are many in this audience who do not know what the National Health Program includes, but you have, of course, heard a great deal of the attitude of American medicine in relation to many of the new experiments in changing the nature of medical practice which are now being tried in the various parts of the United States, some with and some without the approval of the American Medical Association.

The reason for much of the opposition of the American Medical Association to many of these plans is frequently misrepresented, particularly in some of the periodicals devoted to little groups of serious thinkers, publications such as *The Nation Forum*, *The New Republic*, *Daily Worker* and *Liberty*,—I might mention other publications,—but I propose to show you the exact ground on which medicine does oppose some of these experiments and proposes to encourage others.

In order to give you a proper background, I shall take you back quite a few years, not to 1883 when Bismarck first promulgated the compulsory insurance law making medicine the tool of the State, nor to England where Lloyd George, in 1912, in order to win an election, offered the people a compulsory insurance system and the dole. Neither shall I take you to the United States during the period of the World War, when Americans became imbued with the necessity of doing everything on a mass basis, without in many instances understanding the personal character of certain service that might thus be involved. I take you, instead, to the year 1932, when the Committee on the Costs of Medical Care tendered two reports on the state of medical practice in the United States. This committee proposed that all medicine in the United States be reorganized on a voluntary insurance basis, with all practice being conducted around the

hospital,—each hospital having a group of physicians and specialists of various types, with the general practitioners in the community acting as feeders for the hospitals,—and that in each state, a central co-ordinating body be organized to control the practice in the individual states. That proposal met with a certain amount of affirmation from some of the social service leaders of the country, but most of the physicians dissented, as did the House of Delegates of the American Medical Association.

You should know, of course, that the House of Delegates of the American Medical Association is a purely democratic body,—probably more democratic than any other organization in this country,—since it derives its membership directly from the membership of the association in each of the individual States. In each county there is a medical society, and that medical society sends delegates to the governing body of the state society, which in turn sends its delegates, proportionate to the number of physicians holding membership, to the House of Delegates of the American Medical Association.

The House of Delegates of the American Medical Association is the only body in the organization which has the authority to establish policies for American medicine. Neither the president of the Association, the secretary, the manager, the editor nor the board of trustees has any right to make a policy for the American Medical Association. All policies derive from the House of Delegates.

There are, in the United States at the present time, 169,000 physicians licensed to practice medicine. Of this number approximately 145,000 are in the practice of medicine, and of the latter, 111,485 are members of the American Medical Association, this is the largest representation in any professional group in the United States or, in fact, anywhere in the world. Moreover, in the past year, we have added to the membership of the American Medical Association at the very time

Presented before the Manchester Medical Society, Manchester, New Hampshire, December 13, 1938.

†Editor, *Journal of the American Medical Association*.

when it was under fire by a great many of the so-called radical publications. The additional 7000 members since June, 1937, constitute the greatest number added annually to our membership in the history of the organization. I mention that particularly because no doubt you have read, from time to time, of a "revolt" in the American Medical Association by a great number of physicians dissatisfied with the policies of the association, and yet at that very time, the addition to the membership was the largest in any single year in our history.

After the reports of the Committee on the Costs of Medical Care and the Commission on Medical Education in 1932, the entire subject seemed to fall, temporarily, in the state, as Grover Cleveland would have said, of innocuous desuetude. There, it lay for a while. Not much appeared in the newspapers about it because the Nation had other serious problems with which to concern itself. It had, in the first place, a national election, which gave the people considerable concern. After the election, there was the great question of recovery. And the most important question that we must still be concerned with is the question of recovery. I should say here and now, as I said at the National Health Conference in Washington, that the problem of medicine must always be a secondary problem, so long as there are 11,000,000 unemployed in the nation. I said, also, that in 1929, 1928 and 1927, we heard little about the inadequacy of medical service and about the lack of medical care. When the vast majority of the people of the country who are capable of working are given work to do with adequate wages for that work,—not the dole that is thrown out for work that is manufactured,—they are in a democratic country, and capable of choosing for themselves how they will live, what they will read, how they will entertain themselves, and who will take care of them in times of sickness.

After the election in 1932 we began hearing about social security, and about great numbers of people who ought to be provided for. We began talking about the Townsend Plan and the care of the aged.

It is interesting that scientific medicine has made many of these problems for the people of the United States. You did not hear about the care of the aged in 1890. In that year, 27 per cent of the people of the United States were over sixty-five years of age. Today 78 per cent are over sixty-five. Today, there are more people over fifty-five years of age than there are under ten years of age, yet, unfortunately, 95 per cent of the people who are over sixty-five are economically de-

pendent. That, of course, is not the fault of the medical profession, that is, obviously, a fault of the economic system. It is interesting, however, that medicine, through prolonging human life and moving it up from a life expectancy of forty years to one of sixty-two years is primarily responsible for giving us the problem of the care of the aged.

In 1900, the average American worker lost twenty-eight days a year from his work because of illness. Today, the average American worker loses but eight days a year. Take 40,000,000 workers and give each worker twenty additional days of work which he would have had to lose and you have 800,000,000 days of work which would have required additional workers. Exactly as the machine age has added to the problem of unemployment, so has improved medical care for the vast majority of American workers added to it.

When we began talking about the Social Security Law, which was passed in 1934 and 1935, we were concerned, primarily, with the care of the aged, with the relief of unemployment and with the problem of medical care. At that time, a conference was called in Washington, with various committees set up to study various aspects of the problem. The President of the United States appointed the Technical Committee on Medical Care to advise him on the question of how medicine should be dealt with, under the Social Security Law. Edgar Sydenstricker who had worked with the Milbank Fund and with the Committee on the Costs of Medical Care, was chairman of this technical committee, and he advised the President that the problem could be solved by a compulsory sickness insurance plan for the entire nation. However, the President of the United States was apparently not satisfied with that answer to the problem.

A special session of the House of Delegates of the American Medical Association held that year stated it would be opposed to compulsory sickness insurance. The President of the United States then chose from a list of forty-eight names, which were presented to him, twelve men whom he constituted as a special committee. This distinguished committee, led by Dr. Harvey Cushing and including the president of the American Medical Association and ten other distinguished physicians, recommended to the President that there be no compulsory sickness insurance in the Social Security Law. It was not in the Social Security Law. Instead, Congress voted \$10,000,000 a year, to be spent by the United States Public Health Service, in grants made to individual states which would apply equal sums from the state treasuries for the expansion of medicine. This money was

to be for infant and maternal welfare, for the improvement of dentistry, for the care of those with heart disease, the crippled, the blind and the hard of hearing, and for the control of venereal diseases and cancer

Dr Thomas Parran brought the venereal diseases prominently into the limelight. As a result, there was introduced in the last Congress of the United States the La Follette-Bulwinkle Bill. This bill gives, I believe, \$3,000,000 this year, \$5,000,000 next year, \$7,000,000 the following year, and up to \$25,000,000 a year thereafter for the expansion of our control of venereal diseases with provisions for Wassermann examinations and for arsphenamine and other valuable drugs to be given to those who are unable to pay, and in general gives this nation a campaign somewhat comparable to what is being done in England. In addition, because one of the important senators died of cancer, the senators pledged themselves to pass a bill for the improvement of our knowledge of cancer to the tune of \$750,000 a year for five years, to be devoted to a building for the study of cancer and the dissemination of funds to various universities throughout the country making a study of the disease.

We have not lagged far behind in our attention to the specific problems of the Nation. But then if there is any other proof that you need of this fact, I should like to point out that when, presumably, one third of the nation is undernourished and poorly housed and without medical and dental care, the Surgeon-General of the United States made public a report that the sickness and death rates of the United States were the lowest in our history, and that they were much lower than the comparable rates of England, France, Germany or any of the other great nations of the world. If we have a problem, it is not an emergency problem of the type indicated by the articles that have prevailed in our press.

At the same time, the problem of medical care is intimately tied with every other problem of the Nation. Medicine is intimately tied with poverty, bad housing and bad social conditions. The correction of bad housing, poverty and bad social conditions frequently brings about a definite improvement in the health of a great majority of the people in any population.

Bear in mind, also, that medicine is tied intimately with our government in many different aspects. From time to time, various federal committees have considered the problem of a reorganization of the government, in order to bring the questions of medical care under one head. For example, the United States government spends today \$125,000,000

a year on various medical activities. This includes the medical departments of the United States Army and Navy, the United States Public Health Service, which is under the Treasury Department, and the care of the veterans, which is in a special department, it includes, also, the care of the insane to some extent, the education of Negroes in matters of health, the Bureau of Mines, the Food and Drug Administration, the Department of Entomology, which is a subdivision of the Department of Agriculture, and studies on nutrition, which are conducted by the Department of Agriculture. It includes one department whose location is apropos, namely that of maternal welfare in the Department of Labor.<sup>1</sup> In addition there is the whole question of health education and health advertising over the radio, which comes before the Federal Communications Commission. There is also the question of truth in medical advertising, which is governed by the rules of the Federal Trade Commission. All these are related to the health of the American people, they are divided into a great number of departments. And there is the Veterans' Administration.

As the result of recommendations by various committees, half a dozen separate bills were introduced to provide for reorganization. The last congress turned down all of them. One of those bills included the creation of a new department, which was to be known as the Department on Social Welfare and Public Works. From time to time, the name of that was changed, so that it became known, eventually, as the Department of Public Welfare. It was to include three divisions: education, relief, welfare or charity, and medicine and the health of the American people. Promptly, education, as represented by all the leading educators of the country, and particularly by the Catholic educators, objected to having education taken out of the Department of the Interior and put under a department that is concerned with charity and relief.

Medicine also put up quite an objection, but not with success. Medicine was supposed to be left under a welfare worker, who was to be a cabinet member, it is no secret now that Mr. Harry Hopkins, who is in charge of the WPA and a considerable number of other welfare activities of the government, was to have been the man to head this department. I mention this particularly for two reasons: it is well known that Mr. Hopkins is close to the President and also that he has been present at most of the sessions of the cabinet in recent years, notwithstanding that he is not one of its members. He is now Secretary of Commerce. Mr. Hopkins has stated repeatedly in writ-

ing that compulsory sickness insurance is the answer to the medical problem of the country. When a committee of physicians, including 430 doctors, recommended that the American Medical Association discontinue all its opposition to the idea that the states go into the practice of medicine, he said "I hail these distinguished physicians who have indicated that they believe—in contrast to the standpat leaders of the American Medical Association—that the state should control the practice of medicine!"

Then we pass to the next period in which there appeared on the scene the American Foundation studies. Just before they were published we began hearing of the Interdepartmental Committee to Co-ordinate Health and Welfare Activities. This committee was headed by Miss Josephine Roche, who resigned as third assistant secretary of the treasury to take over this new position. This body recently sponsored the National Health Conference, out of which came the National Health Program.

When we read about the Interdepartmental Committee to Co-ordinate Health and Welfare Activities, we thought that it was a committee which was going to have in charge the question of getting together all the different medical activities of the United States government under one head, that perhaps they really intended to have a cabinet officer concerned with the health of the people of the United States, a physician in the cabinet, who would know something about the prevention, diagnosis and treatment of disease, and who would be able to consider this problem with other problems that affect the Government. Of course the care of the people's health, from a financial point of view, is just as important a matter for the Government as is the work covered by the departments of justice, commerce and labor and that of many other departments which have smaller budgets.

Not much attention was paid to the Committee to Co-ordinate Health and Welfare Activities, they went right ahead. Then came the American Foundation studies, conceived as a plan to send letters to 10,000 American physicians, asking their opinions about what was wrong with medical practice in the United States. Out of that effort came the Committee of Physicians, headed by Dr. John P. Peters of Yale University School of Medicine, which proposed certain principles and proposals for the reorganization of medicine. While some of their opinions and proposals were excellent, there was one of which I had considerable doubt. That was Proposal 8, which said that the ultimate direction of medical care should be in the hands of

experts, but which did not define who or what the experts were.

When you get on the witness stand as an expert, you have to prove that you are an expert. But under this particular proposal, it was not stated who the experts were to be. The American Medical Association and the profession have long been of the opinion that the only safety for the American people lies in a proposal which says that the investigation, planning and ultimate direction of medical care must be in the hands of the medical profession. We have tried for many years to keep politics out of medicine, and we have done our utmost to keep medicine out of politics. Our chief battle today is to keep politics—Democratic or Republican, Socialist or Communist, or any other kind of politics—and politicians out of the practice of medicine. There is no safety for the people of this country in a system of medical care controlled and developed primarily as a political weapon. Yet that would seem to be definitely the trend into which many of these people are endeavoring to force us.

After the American Foundation made its report in two large volumes there began to be other discussions. A committee went for luncheon with Mrs. Roosevelt and had a meeting with the President. They endeavored to get physicians to sign petitions supporting their ideas.

Those views came before the House of Delegates of the American Medical Association meeting in 1937, and at that time, they were rejected. At the same time a message, signed by all the officers and the Board of Trustees of the American Medical Association, was sent to the President of the United States indicating the willingness of medicine, as represented by 110,000 physicians, to do its utmost to co-operate with the government in giving all the people of this country the best possible medical service that could be given to them. Nevertheless, there was no specific attempt by the President or any of his secretaries or committees to avail themselves of this offer from the American Medical Association.

Then, before the meeting of the American Medical Association in San Francisco in 1938, we began hearing of a National Health Conference, to be called in Washington to consider the problem of providing the American people with suitable treatment of disease and with suitable preventive medicine.

Shortly thereafter, eight of the officials of the American Medical Association received from Miss Josephine Roche, chairman of the Interdepartmental Committee to Co-ordinate Health and Welfare Activities, an invitation to the National Health

Conference We responded by inviting her to come to the meeting of the American Medical Association in San Francisco She was unable to come, but asked Dr Warren Draper, of the United States Public Health Service, to present her views to the House of Delegates He gave those views The House of Delegates heard them with the greatest of interest and then authorized the eight representatives of the American Medical Association who had been invited to attend the National Health Conference in Washington, in July, and instructed these delegates, of whom I was one, to support the policies established by the House of Delegates of the American Medical Association I repeat this again and again to show you that these policies were not made or established or thought out by one person, but represented the collective view of 110,000 physicians, speaking through their delegates in a representative body

So, we went to the National Health Conference, and we had the opportunity to learn, for the first time, about a new concept that is called the National Health Program Apparently, after the President had appointed the Interdepartmental Committee to Co-ordinate Health and Welfare Activities, it set up a Technical Committee on Medical Care, an advisory committee which made a considerable number of studies and, to use the words of the governmental leaders, drew up a blue print to map the progress of medicine for the next ten years I maintain that in times like these it is rather difficult to make a program for medicine for the next ten years Most presidential administrations are for only eight years Five or six years of the present administration have already gone Yet, here we were to have a blue print to map the progress for the next ten years

Miss Roche said, in her opening speech to the National Health Conference, apparently so instructed by the President "Take this program to the representatives of the American people and to the professions most concerned, and present this program to them, so that we may have their reactions to it"

At the National Health Conference we found approximately 250 representatives of various activities of American life There was one activity which was conspicuously absent I mention this because Miss Roche gave a private dinner to representatives of the press on the first evening of the conference I had the pleasure of attending that dinner and sat beside Miss Roche and near to Miss Katherine Lenroot I said to Miss Roche

I see absent from your conference one conspicuous group in the United States "Which one?" she asked I said "This is still a capitalistic country,

and I see no one representing capital in the United States Where is the president of the American Telephone and Telegraph Company? Where are the representatives of the great textile industry? Where are the representatives of the great shoe manufacturing industry? Where are the representatives of the steel industry and of railroads and banks? Where are all these men? Were they not invited?" Her answer was "Yes, they were, but they did not come Some of them sent the industrial physician in the plant" Apparently, capital did not recognize the significance of this National Health Program

There was one man there who was set forth as representing capital I refer to Mr Charles Taussig, president of the American Molasses Company Mr Taussig took it upon himself to speak for capital in the United States, he said he believed that capital would not be frightened by the immensity of this particular program, and would appreciate that it was the means of saving large sums of money for capital Indeed, he said he would endorse it wholeheartedly

All that first day, we heard speeches of various kinds Some of them poked fun at the medical men The doctors were accused as being bloated plutocrats, with trying to exploit the people Dr Hugh Cabot said thousands of young doctors all over the United States were sitting idle in their offices with nothing to do, and asked why somebody did not put the young doctors to work Of course one of the reasons is that people learn by experience, and sometimes a little experience helps a doctor, older doctors know a little more than the younger ones Not always, of course!

Then the next day at the conference we began to hear the National Health Program The National Health Program proposed, for the first time to any group in the United States, an expenditure of \$850,000,000 a year It was said that they did not expect to get it all the first year, but they were working toward it

That sum of money was to be used, first of all, for expanding preventive medicine in the United States Now, I yield to no one, in my wish to expand preventive medicine in the United States, wherever the need can be shown I believe we cannot have too much preventive medicine, based on sound, scientific knowledge But, I am also a believer in telling the people the truth about preventive medicine, as about everything else concerned with science There are many diseases that we could not prevent next year if you gave us \$850,000,000,000 instead of the \$850,000,000 I have just mentioned We could not, with our present knowledge, prevent a single case of infantile paralysis because we have no exact knowledge

of how the disease is spread from one person to another, and of how the disease shows its earliest symptoms. Of course, we have the suggested symptoms of an increased number of cells in the spinal fluid and of fever conditions resembling a common cold, but by the time we recognize even these symptoms, the disease has spread. A mild case frequently appears in a community in which there has not been a recognized case for a year. So I say that even if we had \$850,000,000,000, we could not guarantee to prevent one case of infantile paralysis. Prevention rests on scientific knowledge, and scientific knowledge should precede the expenditure of vast sums of money on all sorts of diseases whose etiology is not established.

It was proposed, also, that there be complete medical care for the indigent, and for a new group to be known as the "medically indigent." There have been all sorts of arguments about the latter term. We all know that one hundred dollars a month to spend in New York City is barely enough to live on and have anything resembling decent living conditions. I should say at once that such a man is medically indigent. It is impossible for him to save up for an appendicitis operation, a gall-bladder operation, a broken leg or a baby. But these emergencies can happen in any family. A man with one hundred dollars a month to live on in New York City is not prepared for such an emergency. He could be rated as one of the "medically indigent." However, he does not represent a vast majority of the people of the United States. A man living on a farm in southern Georgia and earning a hundred dollars a month, would be what his neighbors call a "big shot." He would be a real citizen in that community, and all the Negroes would tip their hats to him. There can be no single classification of medical indigence in the United States, on the basis of income.

In order to give complete care to the indigent, it is proposed to build 500 additional hospitals in the United States, using governmental money for the purpose, it is also proposed to maintain these hospitals for three years with governmental money, until the communities in which the hospitals are built are capable of taking over these hospitals.

It is claimed that there are approximately 1300 counties in the United States without a good general hospital. However, in contrast the American College of Surgeons, the American Hospital Association and the American Medical Association claim there are only 13 counties in the United States that are more than thirty miles removed from an accepted, general hospital. Furthermore, in 8 of these counties, there is a population of only five people or less per square mile. Naturally they cannot support a hospital, they

could not even keep the beds filled with sick people. Where there are not enough people to support a hospital, even if it were fifty miles away from a good general hospital, you probably would not want to build one.

We have in the United States some 6800 hospitals, and approximately 6218 are registered by the American Medical Association. Seven hundred and twenty-nine of these are acceptable as educational institutions for the training of interns. These hospitals have been, for the past five or six years, from 25 to 35 per cent unoccupied. Why build 500 new hospitals, when a quarter to a third of the available space in existing hospitals is at this moment unoccupied?

Obviously, there might be another answer. This unoccupied space might be used for indigent and medically indigent people, with federal funds and state and county funds available for that purpose. This is another point of view that ought to be considered.

Then, again, when the government builds hospitals, it does not build them the way private industry does. As all of you know, most of the sickness today is cared for in non-profit hospitals. These hospitals were built, in most instances, by communities to provide for their needs or by church organizations, such as the various Catholic orders, Protestant groups, and the Jewish Orthodox and Reform groups. The church organizations have always been active in the building of hospitals, since the care of the sick is a fundamental motive in every great religion.

What will become of these hospitals when the Government starts taking over hospitals, subsidizing some institutions instead of others? Incidentally, they are already deciding which hospital in each community will be given federal money. But why should the government throw its favor to one hospital or another hospital, in relation to the needs of the community?

The Government proposes, when it builds, to spend a lot of money. I am going to mention two of its hospital ventures. In Hot Springs, New Mexico, is a hospital, built at a cost of \$2,500,000, with 90 beds for the care of the crippled children of New Mexico. This particular hospital is named after the mother of the Governor of New Mexico. It is a magnificent hospital, as you may well imagine. When I visited there, it was occupied mostly by Mexican children who had been shipped long distances to Hot Springs, a town of 300 people. Only 30 of the hospital occupants were children from New Mexico. There is no orthopedic surgeon in New Mexico capable of doing the surgery, they rent one from Texas. He goes over, driving one hundred and sixty-five miles, to do the neces-

Those who represented the American Medical Association stood up and said that we had no authority to commit the American Medical Association to anything, that we should have to take this back to our House of Delegates and that they would be asked to make the decision. The House of Delegates approved the legitimate expansion of preventive medicine, wherever the need could be shown locally and the administration could be maintained locally. They disapproved of the 500 hospitals and 500 diagnostic institutions, unless the need could be shown. They favored the utilization of existing institutions before expenditures were made for new institutions. They approved, instead of a compulsory sickness insurance plan for the entire nation under federal or state control, non-profit, voluntary, cash-indemnity insurance plans developed in the individual states or counties. Bear in mind that when you get old and are insured under the government, it does not buy for you food, shelter and clothing, but gives you back the money it took from you because you did not know enough to keep it for yourself. When you are unemployed, it does not buy food, shelter and clothing, but again gives you back the money it took from you. It is always the worker's money. It is deducted from his wages. When the em-

Such a proposition has been unheard of in this country, even Mr Falk was a little doubtful about it, because he said he did not propose to do the whole job at once. First, he wanted to get some of the money in, and then subsidize one state which would consent to be a guinea pig for this

employers pay their share of the social-security tax, they must add it onto the price of their goods, in order to show a reasonable return on their investment, so when the worker buys the goods, he pays that, too. So it all comes out of the worker.

When the government makes a contribution,—bear in mind that it may take a great deal from the rich, but also a great deal from the poor, money spent in taxes is not manufactured money out of the air, it is your money and my money—it is the people's money, the people must have the right to control their own money and expenditures, if we are to remain a democratic nation.

Our chief opposition to compulsory sickness insurance is not so much that it deteriorates the nation. It invariably does that, it has done that in every country in the world where it has been in existence, regardless of what people say. There is no country today which has as high a standard of medical service as prevails in the United States at this moment. Diphtheria control, infant mortality and even maternal care will compare favorably with most of the great nations of the world. Before we change this system, bear in mind that we object to compulsory sickness insurance not only because it degrades the quality of medical service, not only because it enslaves the medical profession of the country,—and it must enslave us,—but because primarily it is the first insidious approach to the breakdown of the democratic system of government. Give anybody the right to interfere thus intimately with the lives of the people, to pay for them the physician, whether or not the physician is selected by the patient, and you have the first step toward totalitarianism. Personally I hate and fear totalitarianism, whether it be under the name of Fascism or Communism. America is the greatest refuge for a free people existing in the world today.

It has been charged that the American Medical Association is a standpat organization, and that it has prevented the people from trying out new forms of medical service. In the United States there are some 300 group-practice clinics, most of them being operated by men who are members of the American Medical Association. There are 300 fraternal and sick-benefit organizations providing cheap medical care for those who want it. There are 2000 industrial medical-service groups. There are 300 universities which give complete medical care, including diagnostic service and treatment to all their students for sums like \$10 or \$12 a year per student. All of these are operated by members of the American Medical Association.

There are hundreds and hundreds of voluntary

insurance plans set up in which the patient receives, in time of his illness, not the services of the doctor, but the cash he put in, in this way he can get the hospital service and the doctor he needs. I maintain that this is not a standpat medical organization. These services were voluntarily developed under the American plan, which keeps the individual as the determiner of his own life.

The American Medical Association has not approved many of the so-called group medical plans because they have not met the standards of the American Medical Association as to their ethical conduct. I maintain that when any group of physicians form themselves into a corporation and send out solicitors from door to door and desk to desk to solicit patients to leave their own doctors, the effort can only lower the quality of medical service in the country. In some of these groups the individual is led to believe that for a certain sum of money he is going to get a complete medical service. But there are extras. They say they will give a blood count, but if you want a sedimentation test or a complement-fixation test,—because you really should have it,—they will give it to you for a little extra. You are only entitled to two chest plates, so if you want serial pictures of the gastrointestinal tract, they will give them to you, but it will cost you extra. They tell you they have used up all the funds available, and charge you extra, after that, it is the corporation that is collecting the funds and not the people. In many of these clinics, it is the hope to make money from the accessories, such as need less supports, needless corsets and all sorts of needless drugs that may be ordered. That is the fault of every one of these systems, the over exploitation of the patients.

When the Group Health Association was established in Washington, it was opposed first of all, because \$40,000 of federal money was used to develop a private corporation. Why should government employees be subsidized by the American government, they ought to pay for medical care out of their wages, exactly the same as anybody else does. Furthermore, when this charge came up in Congress, the committee asked the lawyer for this group whether there were going to be free barbershops and gymnasiums, because, of course, the employees would be better workers if they had these things.

It was pointed out that with the funds available the group could not give a satisfactory medical service. They proposed to charge \$4.00 per month per family, for a complete medical service, including hospitalization. They have since raised the price, as you can read in the current issue of *Survey Graphic*, to \$6.00 per month, they have

added a \$5 00 initiation fee for every man who enters the service, and they have insisted on a complete physical examination of every human being joining the service, because in all these systems there are always patients with chronic ailments who tend to break them down. Enough patients with psoriasis or a mild diabetes, will break down any such system.

Finally, they have eliminated brain surgery and the care of those with tuberculosis and venereal diseases.

Is that a good medical service? We object on the ground that they are not supplying satisfactory medical service to people who think they are going to get it.

Pressure began to be put on the American Medical Association to consent to a great many of these experiments which did not seem to be scientific. This was done in many different ways, one of which was the attempt to indict the American Medical Association with a grand jury in Washington, in order to make the association sign a consent decree. They will not even tell what kind of a consent decree. They said "You write it out and we shall tell you if it is all right." Those indicted did not write it! The House of Delegates, the only body with authority to speak, said to the Board of Trustees of the association, the body that has complete control of the direction and finances "We wish you to oppose this as a blow against scientific medicine, as a blow against the standards of scientific medicine, which have been set up for the benefit of the people, as a blow against the democratic system of government."

The House of Delegates authorized the Board of Trustees to spend every cent possessed by the American Medical Association to carry this even to the courts of last resort, because they conceive this maintenance of a free medical profession as fundamental to the life of the American people and of the American democracy.

At present a conference committee of the House of Delegates of the American Medical Association is meeting with the Interdepartmental Committee to Co-ordinate Health and Welfare Activities, thus far, nothing definite has been concluded. They may yet get together on some of these points of serious disagreement, such as the 500 hospitals, the 500 diagnostic institutions in rural areas and the method of control over the indigent and medically indigent.

If the federal government is to vote vast funds for the medical care of the indigent, the question next arises as to who should have that responsibility.

At present, there are health officers in the individual states and some of the larger individual counties who believe that all this federal money should be turned over to their health departments and that to their departments should be assigned the diagnosis and treatment of disease among the indigent and medically indigent. It is proposed to introduce legislation in connection with this matter in the next Congress, as an amendment to Title 6 of the Social Security Act, to be put under the individual states and, presumably, from them, down to the county health departments.

This is a question which deserves the utmost care and consideration before the American people embark lightly on such a system. As all of you know, there is a great difference of quality and a great amount of inadequacy in many of our state health departments and in many of our county health departments. This is the result of politics being mixed up with these departments far beyond that existing in the welfare divisions and those of public construction. Before we enter upon this sort of thing, we want to know exactly what is to be done. We cannot approve of a nationwide policy of this type, without a great deal of consideration being given to it.

It has been estimated that it will require eight separate and distinct pieces of legislation to make the National Health Program effective, according to the plans set forth. That means that every one of these pieces of legislation must come before the Congress. There have been times in the past when very little time was allowed for hearings. Sometimes, a bill would be brought up in the morning, heard at noontime and passed in the afternoon. If that is to be done with the National Health Program, the people will be committed to something the soundness of which they cannot determine.

Here again, not only the medical profession, but all the people of the country must be alert to what is being done, in order to determine whether or not it is for the good of the American people.

Lastly, I recommend to all of you that you read in the current issue of the *Saturday Evening Post* the article "Rehearsal for State Medicine" by Samuel Lubell and Walter Everett. This article describes the manner in which the Farm Security Administration has been spreading throughout the United States, and now has already established in twenty different states a system of medical practice, largely under state control. The authors make the point that we need no longer argue whether or not we shall have state medicine, or how we shall have it, because in those twenty states, state medicine is here — by what authority, again nobody

knows—because in these states the Farm Security Administration loans money to farmers with which to pay medical bills

However, when you begin hearing of the abuses that have developed in many states under that system, again you will feel that there should be a much more careful study of it and control of it before any state embarks lightly on such a procedure. I have no doubt but that it will give some satisfaction, but in many other places it has worked only to the degradation of the medical profession, to the deterioration of the quality of service and to the encouragement of chiseling of public funds, beyond anything anybody ever thought of in the past

The American public must be aware of these things if they are to fulfill their rights of American citizenship. Being a citizen not only gives you rights and privileges, but it also gives you responsibilities. We have been far too prone in the past to neglect these responsibilities, leaving them to various leaders to look out for us. We must all take an interest in this matter, if we are to protect the rights of the physician, the rights of patients and the advancement of medical science in this country.

It was Abraham Lincoln, who said "A people cannot exist, half-slave and half-free." I tell you no people can exist with a medical profession enslaved to make a politician's holiday.

## MEDICINE AND THE PUBLIC\*

JOHN P. PETERS

NEW HAVEN, CONNECTICUT

IT HAS become a tradition in America that European experience in matters social, economic, and political has no significance for us. This appears to be part of a boastful, flag-waving attitude, well characterized by the slogan "100 per cent American." It is strangely at variance with the placid assumption—no, almost emphatic insistence—that our government and all its agencies are inherently riddled with corruption. Because of these national traits, the American public and the medical profession have remained uninformed or misinformed about European experiments in the dispensation of medical care and suspicious of attempts to initiate similar experiments in this country. There are large numbers in all walks of medical life who see the evils in our medical services and would welcome some reorganization, but how disordered are their views of the direction changes should take is evident from a perusal of "American Medicine," a compilation of their opinions, published by The American Foundation in 1937.

The general defects in the provisions of medical care here and abroad have been analyzed with the greatest care, the broad directions which remedial measures should take have been explored and tested by experiments. Some of the most significant reports of these investigations and experiments are those of the British Royal Com-

mission on National Health Insurance in 1926, Political and Economic Planning on the British Health Services, the Committee on Scottish Health Services, the Committee on the Costs of Medical Care, our own National Health Survey, and that of the Technical Committee, which was presented at the recent National Health Conference.

Reiteration of the same problems and presentation of the same solutions in all these reports must bring conviction that there are certain defects inherent in the nature of modern medicine which transcend boundaries of time and place. Moreover, because medicine has its roots deeply planted in the natural sciences it offers objective data by which these analyses may be tested and from which surveys and projects may be oriented. This potential objectivity also gives hope that more rapid advances may be made in the provision of medical care than in the provision of other basic necessities, such as shelter, food, and clothing, the approaches to which have not been so clearly defined. At least there seems to be good reason for Dr. Hugh Cabot's impatience, expressed in a speech before the National Health Conference to "get over this survey business and get on with the war."

Since the general aspects of the problem have been so thoroughly described by others, they will be merely sketched in broad lines as a background for a more particular discussion of the interests of the medical profession and of certain points which lend national coloring to the problem in the United States. It is recognized that solutions

This article is reprinted in full from the *Virginia Quarterly Review* (15 105-120 1939) with permission of the copyright owner and the author and continues the policy of the *Journal* to present both sides of the various problems that confront the medical profession. The author Dr. John P. Peters is secretary of the Committee of Physicians for the Improvement of Medical Care, Incorporated. Ed.

for these problems cannot be found by physicians alone, but only by the integrated efforts of physicians, other professional groups interested in social welfare, and the government. But physicians occupy a peculiar position as the experts who must implement and execute any plans that may be devised.

The National Health Survey estimated that in 1935-36, in the urban populations investigated, forty per cent of persons came from families with annual incomes less than \$1,000, eighty per cent from families with less than \$2,000. Somewhere in this scale a line can be drawn below which persons are quite unable to pay for medical care without sacrificing the bare necessities of life. The exact location of this line must vary with local conditions which influence the cost of living and with fluctuations in the real value of money. Probably at the time of the survey and for the population investigated, \$1,000 would have been a fair approximation, since over half the population with incomes below this were forced to seek public relief sometime in the course of the year. That forty per cent of our people are too needy to pay for their own medical care is a deplorable and, it may be hoped, a transitory condition connected with the depression. But even in the comparatively prosperous year 1929, only twenty per cent of people came from families with incomes greater than \$3,000 and an equal number belonged to families with less than \$1,000. Although these proportions may vary, nothing short of a revolution will abolish gross inequalities of income and the presence of dire economic need. Any intelligent social welfare program predicated on evolutionary development must take this need for granted and can meet its fluctuations by measuring relief in proportion to income.

The methods by which medical care can be provided must be examined. Attention has already been called to the lowest class, which can afford to pay for no medical care. At the opposite end of the scale is another class whose members can pay individually for all the medical care they may require. Between these two extremes lies the great mass of the population, whose ability to meet costs of medical care varies from the barest minimum to total independence. Unless those in the lower brackets are to accept service of inferior quality they must receive some financial assistance. Even those higher in the scale may, at any time, be reduced by catastrophic illness or disability to the level of indigence. Illness is a hazard of such unpredictable incidence that it cannot be budgeted in advance like most of the prime necessities of life. It is more disastrous than other hazards because it imposes a double penalty. It

deprives the wage earner, at least, of income just when it is most needed to meet the costs of medical care. It is to meet the needs of this great middle class that cost-sharing methods have been devised.

Before these methods are considered, however, a more fundamental question must be decided. Is it to the advantage of society to provide for the health needs of the whole population? From a purely humanitarian standpoint the answer would undoubtedly be affirmative, but humanitarianism sometimes has to yield to economics. Whether a comprehensive program against sickness and disability would yield returns commensurate with its costs is harder to answer. It has been estimated that losses through illness are three or more times as great as expenditures on medical care. Undoubtedly, if these expenditures and the care which they purchase were better organized, the losses could be greatly reduced. Dr. Louis I. Dublin, at the National Health Conference, stated: "Studies which have been thoroughly confirmed show that on the score of the nation's assets, human beings are valued in terms of their productive capacity at five times the value of all other assets." And in another passage: "Again and again health departments, insurance companies, private agencies, have proved to the hilt that there is no finer investment than an investment in the prevention of disease and the care of the sick." These predictions are not without factual support, but if they were merely statements of opinion, it is often opinion rather than fact that determines action. At the National Health Conference, there was unanimous admission of the existence in this country of a great unmet need for medical care and clamorous insistence by all organizations of consumers for some action to meet this need. That care must be provided to the truly indigent by the government is more and more generally accepted. Both the public and the medical profession recognize that physicians cannot supply all the service required gratuitously. Private philanthropic efforts are so dependent upon emotional appeals that they can probably never be effectively organized and directed to meet the demands of such a broad social problem. Governmental aid recommends itself also on the score of equity. Voluntary philanthropy puts a penalty on generosity. The physician can bear the burden only by mulcting his rich patients for the sake of the poor. Moreover, the demand for gratuitous services falls heaviest on those who can least afford to give them, practitioners in needy communities. But all these details become insignificant before the one fundamental fact that the truly needy can

receive medical care only by subsidies derived from the pockets of the wealthy, whether they come in the form of taxes or gifts

If the decision is made to provide for the needy, certain inevitable consequences must be faced. Although poverty is not a sign of delinquency, no premium should be put upon it. Those just above the level of absolute need cannot with justice be treated worse than their poorer brethren. Yet this is inevitable if public aid is given only to the truly needy. Those just above the income boundary of indigence must be reduced to the ranks of public charges by illness or disability before they can receive help. To escape this dilemma many will delay or forego medical care not urgently necessary.

It is to enable persons in this middle class to secure medical care that various cost-sharing methods have been devised. Of these, health insurance deserves major consideration because it has been more widely tested than any other procedure and because in theory, at least, it is more exclusively directed to meeting the costs. This latter point cannot be too much emphasized. Insurance is only a method by which people combine to meet collectively a hazard which, for the individual, has a variable and unpredictable incidence. Because methods for the distribution and administration of medical care under health insurance have rather generally followed a conventional pattern, it has been too much assumed that this pattern is implicit in all health insurance systems. If this were the case, the imminence of health insurance under the growing pressure of public demands would be cause for serious anxiety. There can be little doubt, from the experience in Great Britain and other European countries, that the adoption of health insurance, conventionally patterned, would improve the health of the people at large and the economic status of the physician. The imposition of such a uniform system, however, especially if it gave momentary satisfaction, might ultimately delay progress by checking experimentation. Errors in the present health insurance systems have been discerned and should not be repeated in this country. Some of the chief errors arise, I think, from uniformity in the methods of administering medical care.

If insurance is to cover all those to whom it is applicable it must be compulsory, voluntary health insurance can never provide for the population as a whole. It will assure individuals in any income stratum better care than they could otherwise afford, but it does not abolish the income strata. Consequently, it continues with only slight modification the present order in which care is proportioned to wealth. If the system is to be supported entirely by the insured on

the contributory principle, the same difficulty is encountered. Those in the lowest income brackets can buy only an inferior grade of medicine. The higher standards of care are set, the more limited becomes the class which insurance can cover and the larger grows the group which must receive public support. Employers' contributions are more adapted to provide disability benefits than to purchase medical care, because they can be levied only for the benefit of wage earners to the neglect of the unemployed and dependent members of the population. If a high quality of medical care is to be provided to the whole of the otherwise self-supporting middle class, the premiums of those in the lower income brackets must be supplemented by the government.

Evidently insurance must be scrutinized with some care. If improvement of the health of all the people is the goal, the rich will have to contribute through taxes to provide subsidies for the needy. If the problems of the intermediate class are to be solved by health insurance, premiums must be graduated according to income and must be supplemented by government contributions graduated in the reverse direction. If such a system is subjected to analysis, it at once becomes apparent that insurance is no more than a special form of taxation imposed upon a certain portion of the population. It may have certain advantages over a wholly tax-supported system, but these advantages have not the same weight under all conditions. The recommendations of a large minority of the Scottish Commission are worth quoting in this respect. "The insurance principle becomes continuously less appropriate as the field covered is widened. It has pre-eminent merits as a device for raising money for purposes that are sectional, but when the whole, or substantially the whole, of the population are potential beneficiaries, the retention of the insurance system means the retention of a considerable amount of machinery to achieve an end that might be compassed more simply."

A final element in the question concerns the components of medical care. It is this dimension of the problem with which physicians are chiefly concerned and in which their expert services are indispensable. Methods of financing medical care are primarily the responsibility of economists. The public-spirited and liberal members of the medical profession are solicitous only that sufficient resources be made available without detrimental restrictions. The American Medical Association has expressed itself rather unfelicitously in this connection. The ten official principles of the Association, intended to preserve freedom of action and initiative to its members, place major emphasis on the maintenance of financial com-

petition and the direct passage of fees from patient to physician. This unfortunate attitude will probably prove transitory. It is quite similar to that which the American Medical Association adopted at first towards workmen's compensation and which the British Medical Association initially took towards national health insurance. Both have found their anticipatory fears unwarranted and have learned that remuneration by the government or other intermediary agencies is quite as useful and more dependable than direct compensation from patients. Unhappily these temporary misapprehensions divert attention from the more important subject, the nature and quality of medical care.

The very minimum of medical services is the provision of public health measures. In the beginning, these included only measures to eliminate environmental factors conducive to ill health or physical disability and to prevent the dissemination of contagious diseases, together with the custodial care of the mentally deficient and insane. More recently the care of certain chronic diseases, notably tuberculosis, has been entrusted to the government. Public health departments in certain communities are now engaged in providing diagnostic and therapeutic facilities for physicians, in the rehabilitation of crippled children, in reducing the hazards of maternity and improving the medical care of infants, and in preventing or eliminating industrial hazards. Although the assumption of many of these functions by governmental agencies was contested by the medical profession, at the present time the need for their further expansion under the same auspices is quite generally accepted. Efforts should be made to bring public health services throughout the country up to the high standards which now obtain in only a small part of the nation, and to integrate them more closely with the medical services.

Without sickness or disability benefits as a provision against the economic distress that comes from illness, medical care for the needy or near needy becomes almost an empty gesture. This, private philanthropy has but ill provided and the medical profession cannot give. It is logical to believe that unemployment insurance will soon be stretched to cover it. There is no good reason why unemployment through illness or disability should be distinguished from unemployment incurred for other reasons. Sickness benefits, although they are necessary adjuncts to any comprehensive program for the conservation of health, are not directly medical, but economic measures. Their costs should not be confused with those for medical care, nor should the burden for their administration fall upon physicians. The latter will

undoubtedly have to participate in the process of certifying disability, but their duties in this respect should be minimal lest they be diverted from the more important functions which they alone can serve.

Although the general practitioner is and must remain the fundamental unit in any medical system, the mere distribution of medical attention, exposure of patients to physicians, cannot be interpreted as the provision of adequate care. It is the greatest weakness of national health insurance systems that this has hitherto been almost their sole objective. Undoubtedly they have bettered the general health of the people somewhat by bringing more persons into contact with physicians. In this day, however, a practitioner with only stethoscope and prescription pad can offer but a small part of the benefits which medicine has to contribute. Like every pursuit which is founded on science, medicine has undergone a technological revolution. Today, the scientific practice of medicine demands knowledge, expert technical training, diagnostic and therapeutic facilities undreamed of ten years ago, the armamentarium which it will require in another ten years is beyond prediction. If the world is to reap the benefits of these scientific discoveries, they must be made available to the public.

It is hard to see how this can be efficiently accomplished without some departure from the present individualistic system of practice. No one man could acquire the knowledge and technical proficiency to practice all the skills of medicine, even if he had the money to possess and the time to manipulate all the apparatus. The general practitioner is to be congratulated if he can keep aware of new developments and recognize the indications for their use. Specialization, especially in the use of technical procedures, has become essential. However, specialties should not be practiced for their own sake, they are merely ancillary to the broader functions of medicine and must be co-ordinated by some method. Co-ordination is essential for another reason. The physical equipment required for the modern practice of medicine is so costly that it becomes ever more important that it be utilized with the greatest efficiency. The overhead expense incurred in the purchase, maintenance and operation of this apparatus, which makes up no small part of the cost of specialist services, becomes unduly large under an individualistic competitive system because of the reduplication of equipment that such a system entails. It is almost too obvious to mention that under even the most efficient system, with these accessories and with the greater educational preparation which is demand-

ed of physicians, doctors can no longer afford to give medical care gratuitously to the increasing proportion of the population that cannot afford to purchase it

In spite of the apparently inevitable implications of medical evolution, efforts at co-ordination are still in the most elementary stage. Physicians trained in various specialties have formed private groups which can offer more comprehensive service than any individual in the group could give alone. The economies effected by such voluntary aggregations, even if its members are activated by the highest motives, under a competitive system with fees more or less standardized, accrue to the physicians rather than to the patients. The formation of groups or co-operative organizations which provide general care on a prepayment basis, although in theory it would seem a sound procedure, has met the bitterest opposition of organized medicine. The reasons advanced to explain this opposition seem to the initiated not altogether consistent nor convincing. It is claimed that it will destroy the professional status of the physician, as if medicine were still comparable to the law, a pursuit that can be conducted without special properties or technical aids. There are strong objections to the exploitation of physicians and patients for profit and to the control of groups by organizations or persons with interests foreign to those of the patient. Fear of such dangers and fear lest the element of personal responsibility be removed from the physician justify injunctions against the corporate practice of medicine. Advertising and soliciting patients are likely to have a degrading influence. Experiments have proved, however, that these dangers and nuisances can be avoided in co-operative enterprises instituted to furnish medical care to organized groups of the population, so long as no third party is permitted to profit from the undertaking. If insistence that each patient have the right to free choice of a physician expresses more than a desire to preserve unrestricted competition among physicians, no one can dispute the remark made by Dr C. E. A. Winslow before the National Health Conference: "I have great sympathy with the principle of freedom of choice of physicians, but I should like to point out that any acceptable definition of freedom of choice of physicians must include the right of a group of patients to choose a group of physicians of their choice. Any artificial attempts to interfere with that freedom cannot stand." The following passage from the latest official resolution of the American Medical Association concerning hospital insurance is at best an inept manner of conveying the idea that the sacred personal relation between patient and

physician must be preserved. "If for any reason it is found desirable or necessary to include special medical services such as anesthesia, radiology, pathology or medical services provided by out-patient departments, these services may be included only on the condition that specified cash payments be made by the hospitalization organization directly to the subscribers for the cost of the service." My respect for American physicians will not allow me to admit that their services will be influenced predominantly by the hands through which they receive their compensation. But the emphasis in their resolutions and in the statements of their official spokesmen has been unfortunately placed. Equally unfelicitous is the insinuation that if salaries are substituted for fees the quality of medical service will deteriorate. Such an insinuation is not even entirely ingenuous. For generations young men have served on salaries without objection as assistants to their professional elders. Specialists employ assistants on salary without criticism. Our public hospitals and universities present, among their salaried physicians, examples of unsurpassed industry and enthusiasm.

The great scientific achievements of America and the high standards of its medical schools are cited as reasons for eschewing change in the present methods of medical practice, as if the two were related. How much credit for the rapid advances in investigation and education should redound to the general organization of medicine is debatable, that the tempo of these advances would have been retarded, had there been less co-operative activity, cannot be questioned. Nor can there be any doubt that the association of specialists, often on salary, in our teaching hospitals has greatly accelerated the elucidation of clinical problems. The exemplary nature of the clinical work done in such institutions and by similar groups less intimately connected with universities—such as the Mayo Clinic—has won them international recognition. Is it not the height of paradox to obstruct wider dissemination of the group system when our medical schools are teaching and demonstrating its practical advantages?

Co-operative and group health systems are steadily increasing in numbers and strength. Their extension was recommended by the majority of the Committee on the Costs of Medical Care. They seem peculiarly adapted to meet the requirements of certain portions of the population and certain geographical areas. There is no reason to believe that the group principle could not function under an insurance system or one that was financed by taxation. A movement so obviously conducive to efficiency and economy will not be checked by mere obstructive tactics. It would ap-

pear to be better policy for the medical profession to anticipate inevitable trends. If they participate in experimentation they may influence its direction. If the standards of medical service and the personnel of co-operative ventures were not satisfactory—which has not been demonstrated—some blame would attach to the medical societies which have discouraged or prohibited their members from entering such ventures. If co-operatives encroach upon established practice, practitioners will not better their position by abstaining from participation. If they reduce some incomes, they may increase the general level of income and offer greater security. If, by promoting efficiency, they increase the capacity of physicians to care for patients, they also increase the capacity of patients to pay for these services and enlarge the demand for services. Individual choice of physician may be conserved so far as it is compatible with the best service. Finally, the union of a group of men in a common enterprise furthers education through mutual stimulation and criticism. The best patterns for such enterprises undoubtedly remain to be found, no single pattern is likely to prove suitable for all communities. But the general principle that a higher quality of medicine can be provided by a group of physicians with individually differentiated training and functions, working in co-ordination, than by individual physicians operating competitively, has sound theoretical and practical support.

Hospitals must be included in the medical services that are contemplated and must be made generally accessible. A recent spot map showing a hospital within thirty miles of every person outside of the uninhabitable portions of the Rockies is quite meaningless. It is clear from the report of the Technical Committee, eloquently confirmed by numerous speakers at the National Health Conference, that there are not sufficient hospitals accessible to the members of communities about them, equipped and staffed to provide care of high quality. Construction of further hospitals alone will not meet the need, those already in existence, both public and private, must be improved and made more available. The services of modern hospitals are not confined to their inmates. They provide, in addition, diagnostic and therapeutic facilities to their out-patients and for the patients of physicians in the communities in which they are located.

Finally, no program for the improvement of medical care can neglect education and investigation, the institutions which train the professional personnel and develop newer and more efficient methods to prevent and combat disease. Support for these institutions must be measured out with

no niggardly hand to meet the demand for more and finer products. And the process of education must not stop at the exit from the school. Under a purely competitive economy, the obligation of the medical schools to meet the demand for "refresher" courses for practitioners out of their present meager means and by adding burdens to their already overtaxed faculties is questionable. If they are to satisfy this obligation under any system, further resources must be found. This burden will be partly removed by the formation of properly constituted groups and medical centers and adequate provision of hospitals. A modern hospital or clinic, properly staffed, equipped, and conducted, has all the potentialities of an educational institution. Moreover, the efficient organization of work should grant the workers more opportunity and incentive for self-improvement without impairing accomplishment. It is to be anticipated also that those gifted with curiosity and originality will devote some of this time to investigations that will further speed the advance of medicine.

Means must be found by which personnel and facilities may be selected on the basis of competence and quality, standards, not on stereotyped models, must be established, authoritative bodies, which can exercise judicial powers without fear of political pressure from within or without the medical profession, must be constituted. Although professional or trade organizations have been found inherently unfitted to assume such functions, the medical organization, if it would rid itself of a jealously defensive attitude, could do much to forward discovery of a proper formula.

At present federal, state, county, and city governments all share the load of public health services. No one of them can be eliminated. There is reason to believe that the part that all will play in the provision of medical care will increase. If this is so, the allocation of responsibility is a matter for intelligent consideration, not one that should be predetermined by political ballyhoo or unreasoning prejudice. It is feared that intrusion of government in medical affairs will necessarily bring bureaucracy, regimentation, corruption, and inefficiency. Federal intrusion is particularly feared because of its potential magnitude. Those who admit the necessity for federal financial aid prefer that administrative control be left to the states and counties. Although local autonomy seems to offer more chance for intelligent variation by constituting units of manageable proportions, our experience with social security gives little reason to believe that political inefficiency and corruption will be eliminated by entrusting administration

to local governments. If federal funds are to be spent, the federal government must reserve some right to condition the manner in which they are expended. All these anticipations would be robbed of some of their menace if those with expert knowledge, especially physicians, would enter wholeheartedly into the projection of plans, instead of confining themselves to objections.

Certain virtues our federal government has displayed a great interest in social and economic problems and a capacity to probe them by investigation. There is not space to discuss in detail the National Health Survey, the Report of the Technical Committee, nor the comprehensive program for the improvement of medical care presented before the National Health Conference, but certain characteristics of this program must be stressed. Now that attention is no longer focused on the details that aroused personal and factional animosities at the Conference, it is seen that the program bears the marks of statesmanship, rising above political expediency. The problem is clearly defined and measures for the treatment of each major phase are outlined. The federal government is not given undue predominance, administration is entrusted to local and state authorities, proposals are stated in general terms only, the means to implement them and the machinery to execute them are wisely consigned to further discussion and experiment, gradual, evolutionary develop-

ment is contemplated. Provision of some kind is made for each of the components of medical care, with proposals for financing them in accordance with the economic status of the population. Undoubtedly, objections can be raised to details of the plan, but it provides a basis for discussion hitherto unequaled. Consumer groups have almost unanimously accepted its chief provisions, hailing especially those that deal with means of providing care to the middle class on cost-sharing principles. On the other hand, it is just these proposals that the American Medical Association officially refuses to accept. It admits in principle the necessity for all the others. It even acknowledges the desirability of cash benefits for disability due to sickness. A certain amount of experimentation with voluntary insurance, carefully conditioned, it is willing to countenance. But compulsory health insurance or other comprehensive programs to meet the needs of the marginal income class are excluded from consideration. Such a division between laymen and physicians can have only deplorable results. The temper of the public will not brook complete inaction. Will organized medicine, by offering co-operation, aid in the development of an intelligent comprehensive plan for the provision of medical care, or will it wait until some system is imposed upon the country with defects that can be removed only by years of further effort?

## A SURGICAL APPROACH FOR LIGATION OF A PATENT DUCTUS ARTERIOSUS\*

ROBERT E. GROSS, M.D.†

BOSTON

THE last three decades have brought forth outstanding achievements in cardiac surgery. Beginning with the first successful suture of a human myocardium by Rehn<sup>12</sup> in 1896, this branch of traumatic surgery was further developed by Beck,<sup>2</sup> Elkin<sup>9</sup> and Bigger,<sup>6</sup> who contributed greatly to the repair of wounds of the heart inflicted by gunshot or stabbing. The early work of Schmieden<sup>14, 15</sup> and the later advances of Rehn<sup>13</sup> and Churchill<sup>8</sup> have placed the relief of constrictive pericarditis on a practical basis which is now productive of highly successful results. Cutler's<sup>7</sup> pioneer operations on stenosed mitral valves have given a new impetus to the designing of procedures for direct attack on cardiac lesions. More recently

Beck<sup>3, 4</sup> and Davies, Mansell and O'Shaughnessy<sup>5</sup> have been able to establish an accessory blood supply to the myocardium in patients with coronary sclerosis or occlusion. However, the exploitation of congenital defects of the heart has thus far been limited to the cardiac envelope. In this field Ladd<sup>11</sup> has successfully repaired a diaphragmatic hernia associated with absent pericardium in which there was herniation of intestines into the thoracic cage around the heart. It now appears that another congenital abnormality, namely a patent ductus arteriosus, might well be brought to the surgeon's attention, for it is probable that the closure of this persisting and anomalous vessel would be a worthwhile undertaking. This paper presents a method whereby the ligation of a patent ductus may be accomplished.

Many of those born with a patent ductus live

\*From the Laboratory of Surgical Research, Harvard Medical School and the Department of Surgery, Children's Hospital, Boston.  
†Instructor in surgery, Harvard Medical School, resident surgeon, Children's Hospital and Peter Bent Brigham Hospital.

for fifty, sixty or more years without any serious impairment of health, and complain of little more than moderate dyspnea after physical exertion. However, such a span of life is not allotted to all these patients, for the statistics of Abbott<sup>1</sup> show that in a series of 92 autopsied subjects who had this lesion (and who had no other associated anomaly) the average age of death was twenty-four. Twenty-one of these patients died of subacute bacterial endarteritis of the pulmonary artery, 24 died of slow cardiac decompensation, and 16 died of sudden cardiac failure. These figures indicate that

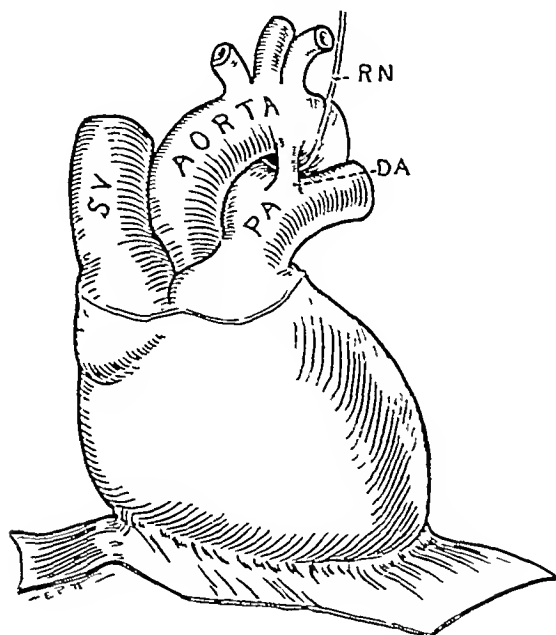

FIGURE 1 Sketch of Heart and Great Vessels Showing Position of the Ductus Arteriosus in Man

*The aortic end of the ductus lies opposite the origin of the left subclavian artery. The pulmonic end of the ductus opens far back on the pulmonic artery near the origin of the left pulmonic artery. In some instances the ductus communicates with the left pulmonic artery proper rather than with the main trunk. The left recurrent nerve curves around the aortic arch passing posterior to the ductus. D.A., ductus arteriosus. R.N., recurrent nerve. SV., superior vena cava.*

the child or adolescent person who has a patent ductus has about a 66 per cent chance of dying prematurely because of the presence of this anomalous vessel and the complications to which it may lead. Therefore, surgical procedures which are designed to obliterate the ductus could carry a very high mortality and still offer the patient a better prognosis than if his lesion were left untreated. It is reasonable to believe that an experienced operator could explore the ductus and ligate it with a mortality rate of 10 per cent or less.

One might argue that there are obstacles which militate against surgical obliteration of a patent ductus. For example, there may be some associated anomaly such as coarctation of the aorta proximal to the aortic opening of the ductus, or congenital stenosis of the pulmonic valve. In either case the persistence of the ductus probably represents a compensatory mechanism and surgical closure would be a fatal procedure, or at least would further embarrass an impaired circulatory apparatus. In the series of 242 cases of patent ductus reviewed by Abbott 150 cases showed associated anomalies of importance but the more serious ones usually led to death in the early weeks or months of life. Thus, if surgical intervention for ligating patent ductus is deferred until children are six or seven years old, the more complicated cases are ipso facto weeded out. Even then it is necessary to exercise close judgment in the selection of cases for operation, in order to select the individual who has a patent ductus and yet has no other serious abnormality.

The objection might be raised that surgical closure of a ductus is undesirable because the persistence of the passageway is prima-facie evidence that it is needed and would have closed off spontaneously if it had not been. The answers to this objection are twofold: first, there are many case reports with careful autopsy examinations appearing in the literature which show that the ductus can persist as a solitary lesion; secondly, if for any reason the ductus has failed to close in the early weeks of life, subsequent closure by natural processes is more difficult, because the vessel gradually becomes so dilated that its walls do not fall together and coalesce so easily as they do in the newborn.

With these considerations in mind, it seemed well to seek a way in which the ductus could be approached and ligated without undue risk. The first efforts to explore the possible routes were made on human postmortem material. The classic mediastinal approach was made anteriorly, portions of the second, third and fourth ribs on the left were removed and adjacent portions of the sternum were rongeuured away, employing much the same exposure as that used for removing emboli from the pulmonary artery. However, it soon became apparent that this exposure was unsatisfactory because the bony orifice of the wound (in children) was too small unless a very extensive and time-consuming removal of most of the sternum was undertaken. Furthermore, the position of the ductus in some cases was so posterior on the aortic arch and the pulmonic artery that with the anterior approach the operator would be work-

ing in the apex of a deep wound, where it would be difficult to avoid injury to the recurrent laryngeal nerve, and where it would be hard to control any bleeding which might occur

Subsequent investigation led me to the belief that the ductus could be more easily approached via the left pleural cavity (Fig 2) With this

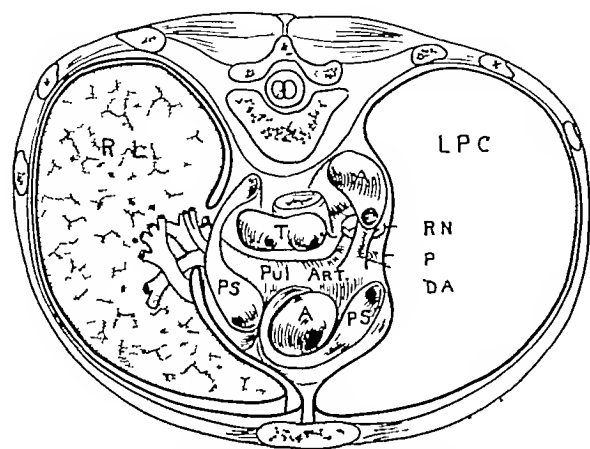

FIGURE 2 Sketch of Horizontal Section through Human Thorax at Level of Fifth Vertebral Body Showing Relations of Aorta Pulmonic Artery Ductus Arteriosus and the Left Pleural Cavity

The left pleural cavity is shown as being empty, for if the left lung is allowed to collapse by opening the pleural cavity the lung falls downward below this horizontal plane. Surgical attack on the ductus can then be readily made through the left pleural cavity merely by incising the parietal pleura which covers the mediastinum in this region. After the ductus is ligated, the left lung can be re-expanded and the chest wall closed. A, ascending and descending aorta. D.A., ductus arteriosus. LPC, left pleural cavity. P, parietal pleura covering the mediastinum above the lung root, PS, pericardial sac. PUL ART, pulmonary artery, R.L., right lung. T, trachea at its bifurcation.

route through the lateral side of the chest, the lung can be allowed to collapse temporarily. The pleura on the mediastinal surface of the pleural cavity can then be incised and a direct and excellent view of the aortic arch, the pulmonary artery and the ductus can be obtained. The exposure by this approach is excellent, and is adequate to control any emergency which may arise, such as bleeding from some small neighboring vessel. After ligation or division of the ductus has been effected, the lung can be expanded with positive pressure through an indwelling tracheal catheter and the thoracic cage can be closed.

The feasibility of such a proposal was demonstrated on dogs. After reviewing the local anatomic relation on several canine cadavers, the operative steps were performed on twenty living mongrel dogs. Intravenous Nembutal anesthesia (35

mg per kilogram of body weight) was employed in each case, and an intratracheal catheter was connected with an Erlanger positive pressure apparatus, so that the latter would be available after the thorax was opened. With the left anterolateral aspect of the dog's chest upward, and the left fore leg pulled up over the head, incision was made over the third intercostal space from the sternum to the left midaxillary line. Incision was carried through the lower portions of the pectoral muscles and through the intercostal muscles to gain entrance to the chest. The third and fourth ribs were now cut through at their respective costochondral junctions so that the ribs might be spread widely apart with a self-retaining retractor. A moist gauze sponge was then laid over the lung, which collapsed into the inferior part of the pleural cavity, thus affording an excellent view of the mediastinum in its left lateral aspect. The pleural covering of the mediastinum was incised longitudinally and the ligamentum arteriosum (the obliterated remnants of the ductus of Botalli) was freed around its circumference so that it could be doubly clamped, divided and tied. The left recurrent laryngeal nerve could be identified as it coursed around the arch posterior to the ligamentum arteriosum, and this nerve could be left undisturbed during the manipulations. The thorax was now closed by bringing together the intercostal muscles—expanding the lung with positive pressure before tightening up the last stitch. The repair of the chest wall was completed by suturing the divided muscles and skin.

In no case was a patent ductus found in a dog. However, the rehearsal of the operative steps in this fashion amply demonstrated that an excellent view of the ductus region could be obtained by this route, that the areolar tissues between the aortic arch and the pulmonic artery could be safely dissected in spite of the rhythmical beating of these vessels and the respiratory motions of the thorax, that the collapse of the lung causes no immediate or subsequent embarrassment if the lung was re-expanded at the end of the operation, and that this procedure gave no operative mortality in dogs.

The success of the above exposures on dogs appeared to be substantiated by practicing the operative steps on a number of cadavers of children varying from three months to twelve years of age. Incision through the left third intercostal space from the sternum around to the mid-axillary line places the wound at about the optimum level for viewing the aortic arch from the side. Division of the rib above this incision at its costochondral junction and insertion of a self-retaining rib spreader greatly increases the size of the wound.

To approach this portion of the third intercostal space, the skin incision can be made directly over the area in the male, but in the female it is better for cosmetic reasons to make a much lower cutaneous opening—cutting well below the breast tissue, and then turning upward a flap of skin and

covering of the mediastinum between these four structures brings one immediately down on the ductus arteriosus. It is best to incise this pleural covering in a cephalocaudal direction, rather than transversely, for this involves less danger of severing the recurrent laryngeal nerve and the cardiac

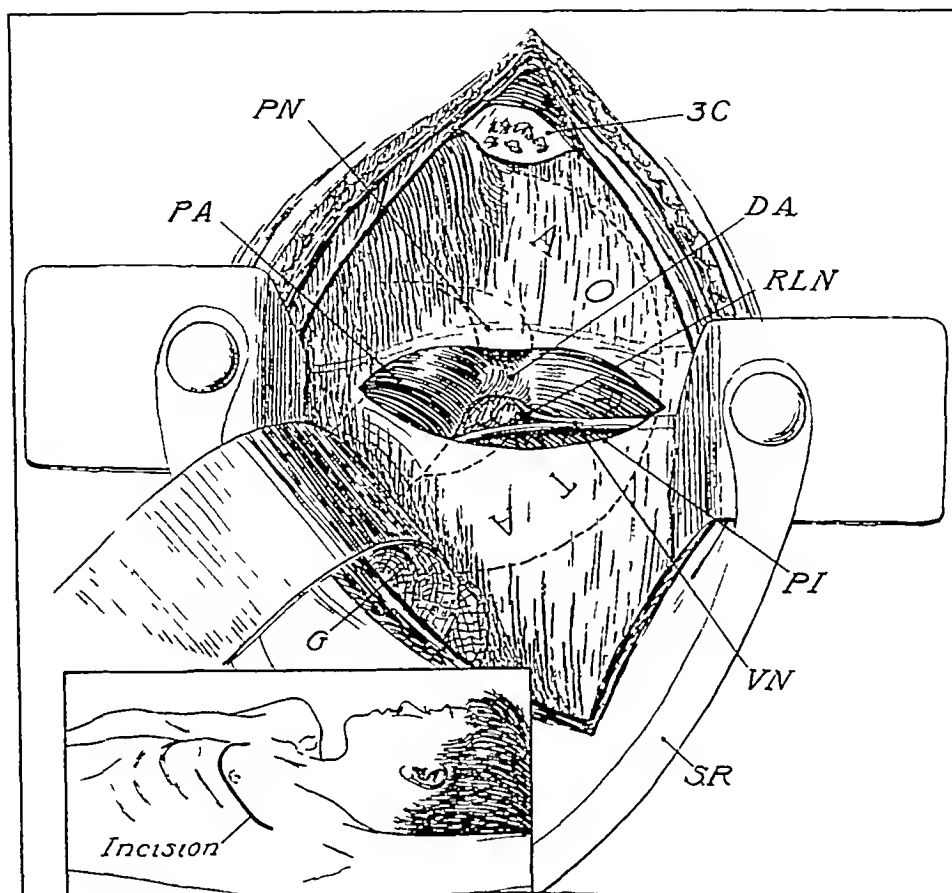

FIGURE 3 Sketch Showing View of the Human Mediastinum as Seen at Operation by an Anterolateral Approach through the Left Pleural Cavity

Incision is made through the third interspace. The third costal cartilage is cut and the third rib is retracted upward. The lung is held down in the bottom of the pleural cavity with a ribbon retractor. The pleural covering of the mediastinum is incised, and the ductus arteriosus is adequately exposed between the aorta and pulmonary artery. 3C., cut end of third costal cartilage; DA, ductus arteriosus; G, gauze pack over compressed lung; P.A., pulmonary artery; PI, pleural incision; PN, phrenic nerve; RLN, recurrent laryngeal nerve; S.R., self-retaining retractor; VN, vagus nerve. The insert shows the position of the skin incision.

muscle until the third intercostal space is reached.

When the parietal pleura is opened the lung collapses and is packed away in the middle and inferior portions of the pleural cavity with moist sponges, this permits a wide view of the mediastinum above the level of the lung hilum. Excellent landmarks (Fig 3) to the desired ductus area are the aortic arch above, the left pulmonary artery below, the phrenic nerve anteriorly and the vagus nerve posteriorly. Incision of the pleural

fibers from the vagus nerve. For a similar reason, it is best to keep this incision somewhat anteriorly toward the phrenic nerve and peel the pleura backward, allowing it to carry with it any small cardiac fibers which are adherent to its surface but too small to be seen. In the great majority of cases the region between the aortic arch and pulmonary artery can be exposed without opening the pericardial sac, but in a few of the cadaver specimens the pericardium had a very high reflection

ing in the apex of a deep wound, where it would be difficult to avoid injury to the recurrent laryngeal nerve, and where it would be hard to control any bleeding which might occur

Subsequent investigation led me to the belief that the ductus could be more easily approached via the left pleural cavity (Fig 2) With this

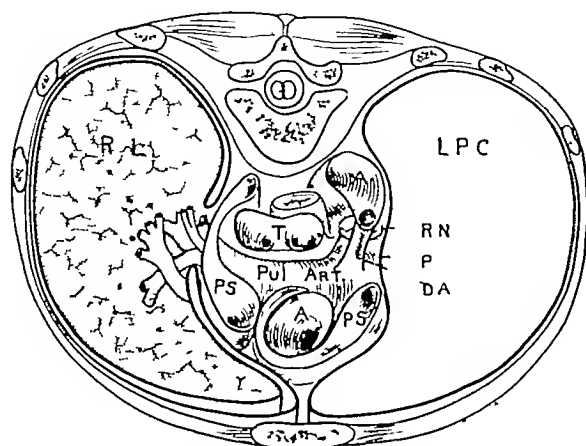

FIGURE 2 Sketch of Horizontal Section through Human Thorax at Level of Fifth Vertebral Body Showing Relations of Aorta, Pulmonic Artery Ductus Arteriosus and the Left Pleural Cavity

The left pleural cavity is shown as being empty, for if the left lung is allowed to collapse by opening the pleural cavity the lung falls downward below this horizontal plane. Surgical attack on the ductus can then be readily made through the left pleural cavity merely by incising the parietal pleura which covers the mediastinum in this region. After the ductus is ligated the left lung can be re-expanded and the chest wall closed. The success of the above exposures on dogs appeared to be substantiated by practicing the operative steps on a number of cadavers of children varying from three months to twelve years of age. Incision through the left third intercostal space from the sternum around to the mid axillary line places the wound at about the optimum level for viewing the aortic arch from the side. Division of the rib above this incision at its costochondral junction and insertion of a self-retaining rib spreader greatly increases the size of the wound

## CITRATES IN THE TREATMENT OF INFANTILE RICKETS\*

ALFRED T SHOHL, MD,† AND ALLAN M BUTLER, MD‡

BOSTON

TREATMENT of infantile rickets with potent preparations of vitamin D leaves little to be desired. Indeed, the resultant cure is so satisfactory that it has tended to prevent an advance in our understanding of all the factors concerned in the pathogenesis of the condition. Presumably vitamin D cures rickets primarily by increasing the absorption of calcium, which in turn permits an increased absorption of phosphorus.<sup>1</sup> But other factors besides vitamin D affect the absorption of calcium and phosphorus and the healing of rickets. The most important of these are the levels and ratios of calcium and phosphorus in the diet, the acid-base value of the diet and its content of certain organic acids, especially citrates and to a lesser extent tartrates. The evidence for the last two of these factors is largely derived from animal experiments. It has recently been reviewed,<sup>2, 3</sup> and need not be presented here.

Although much has been learned about rickets from animal experiments, information derived therefrom can be applied to infantile rickets only by analogy. We have therefore been eager to try citrate mixtures, so effective in curing rickets in rats,<sup>3</sup> in the treatment of infantile rickets. Aside from the theoretical interest, the cure of rickets by factors other than vitamin D is of specific interest in the treatment of rickets resistant to vitamin D,<sup>4</sup> and perhaps other disturbances of calcium and phosphorus metabolism. Albright and Sulikowitch<sup>5</sup> have observed beneficial results from the administration of citrate mixtures in a patient with nephrocalcinosis. Moreover, such factors are of general significance for an understanding of the principles determining the adequacy of diets. The beneficial effects of large amounts of orange juice on calcium and phosphorus retentions, as observed by Hanke<sup>6</sup> and Chaney and Blunt,<sup>7</sup> may have to be re-evaluated in terms of the citrate content of such diets.

The paucity of untreated rachitic subjects at this clinic during the past two years has made available only 2 patients with infantile rickets in whom citrate mixtures could be used as the anti-rachitic agent. We are fully aware that neither case was ideal for such experimental work. The

complicating factors are given in the case histories and considered in the discussion. The prospect of obtaining more satisfactory cases in the near future is so doubtful that these preliminary results are reported so that this therapy may be given further trial by others.

*Case 1* (No I 22318) E S, an 11-month-old Negress, entered the hospital with the chief complaint of an upper respiratory infection of six days duration, and cough, fever, anorexia and vomiting of 2 days duration. She was born at term after a normal labor and weighed 8 pounds. She had never received cod liver oil or vitamin D concentrate.

Physical examination showed a well-developed and nourished infant with pronounced parietal and frontal bossing, an anterior fontanelle of 6 cm., rachitic metaphyses at both wrists and rachitic rosary. The temperature was 103°F, pulse 150 and respirations 50. The pharynx and both eardrums were red. There were signs of bronchitis throughout both lungs. There was a moderate sized umbilical hernia. Roentgenograms showed advanced active rickets and generalized decalcification.

The patient was put on a non-irradiated evaporated milk, Karo, and water formula and given 50 mg. of ascorbic acid per day, but no vitamin D. Hemolytic streptococci were recovered the next day from a throat culture and 20 gr. of sulfanilamide were given by mouth, and thereafter for the next 12 days 5 gr. every 6 hours. At the same time a small area of pneumonic consolidation of the lung was demonstrated by roentgenograms. The temperature fell to within normal limits within 24 hours and remained normal throughout the hospital stay. The signs of pneumonia rapidly cleared.

On the 9th day a citric acid sodium citrate mixture of 20 cc. of molar citric acid\* and 30 cc. of molar sodium citrate† was added to the formula as a diluent for the milk. This was continued for the following 36 days. During this period the patient gained in weight from 16.5 to 18.5 pounds.

Table 1 gives the concentrations of serum calcium, inorganic phosphorus, phosphatase and protein, the roentgenographic information concerning the rachitic changes and the diet during hospitalization. On the 45th day the rickets had healed so satisfactorily that the citrate mixture was discontinued, percomorph oil was prescribed and the patient was discharged home.

*Case 2* (No I 22224) D D, a 5 month-old Negro was admitted to the hospital with a chronic cough of 6 weeks' duration. The baby was born following a normal labor and weighed 8.5 pounds. He was said to have received daily ½ teaspoonful of cod liver oil and 2 teaspoonfuls of orange juice during the 4 weeks before admission. He was well until 6 weeks before admission, when he developed an upper respiratory infection. During the 2 weeks preceding entry he lost 2 pounds in weight.

Physical examination showed a baby with a rasping

$\text{H}_3\text{C}_6\text{H}_5\text{O}_7 \cdot 3 \text{H}_2\text{O}$  210 gm. per liter

$\text{Na}_2\text{C}_6\text{H}_5\text{O}_7 \cdot 5\frac{1}{2} \text{H}_2\text{O}$  357 gm. per liter  $\text{Na}_2\text{C}_6\text{H}_5\text{O}_7 \cdot 2 \text{H}_2\text{O}$  294 gm. per liter

Assistant professor of pediatrics, Harvard Medical School.

and had to be opened in order to reach the ductus. While opening of the pericardium necessitates some loss of the pericardial fluid, it should not add any particular risk to the operation.

After the arch and the pulmonic conus are exposed, these two structures can be separated by blunt dissection, stripping away the areolar tissue which loosely binds them together. The most important structure to identify and scrupulously avoid is the left recurrent laryngeal nerve which loops around the aortic arch, passing lateral and posterior to the ductus. This structure may lie within a few millimeters of the ductus, but it can be readily freed and can be pushed posteriorly if necessary.

In no case have I encountered any difficulty in identifying this nerve in human material (in contrast to the dog), and operators should have no trouble in locating it and preserving it intact.

The diameter of the persistent ductus has little bearing on the possibility of ligating it, for a vessel 1 cm in diameter could be obliterated almost as easily as could a vessel 2 or 3 mm in diameter. However, the length of the ductus is of considerable importance. If the vessel is 0.5 cm or more in length it can be easily freed around its circumference and a tie placed on it, whereas a shorter vessel may defeat all efforts to free it and may make it impossible to place a circumambient ligature with any degree of safety. Should one be forced to deal with a ductus which is very wide and very short, it would probably be necessary to divide the ductus completely and to suture the defects in the aorta and the pulmonic arteries individually.

After the ductus is tied, the pleural covering of the mediastinum can be rapidly closed with a few interrupted stitches in order to smooth off the interior of the pleural cavity at this point. The thorax is then closed with a continuous catgut suture to the intercostal muscles, but before tightening the last stitch the lung is completely expanded by increasing the intratracheal pressure via the anesthesia machine. The severed digitations of the pectoralis muscles are now brought together to restore their continuity, and the subcutaneous fascia and skin are approximated with interrupted sutures.

The anesthetic in human cases may be ether, but Cyclopropane is preferable. The use of a gas machine with either an intubating tracheal catheter or a closely fitting face mask is essential, because the anesthetist must be prepared at all times to give positive pressure when needed. This machine is of particular value when the chest is being closed and it is desired to re-expand the lung.

This method of exploring and ligating the ductus is a practical procedure which can be employed

for human beings, for I have recently undertaken the operation on 4 patients (Fig 3). Each of them survived the operation and had a remarkably smooth postoperative course without complications. The loud murmurs heard before operation have been reduced to minimal ones in 2 cases, and have completely disappeared in the other 2, in which double ligature was employed. The precordial thrill has disappeared in every case. In 2 patients there has been a reduction in the size of the heart postoperatively. In each case the low preoperative diastolic pressure has permanently risen 25 to 35 mm of mercury to a normal level. The success of the procedure suggests that the operation should be performed in certain selected cases as a safeguard against the dangers of subacute bacterial endocarditis or cardiac decompensation.

#### SUMMARY

The rationale for proposing surgical ligation of a patent ductus arteriosus is briefly presented. It appears that a number of individuals may enjoy a long life with this lesion and yet not suffer any important consequence. However, the adolescent child who possesses this abnormality faces such a great probability of serious complications arising from the patent ductus that surgical attempts to close the persisting vessel seem definitely justifiable.

A method has been devised whereby the patent ductus arteriosus can be adequately exposed by a lateral approach through the left pleural cavity. The safety of this exposure was amply demonstrated by practicing and perfecting the procedure on dogs. The superiority of the lateral route as compared to an anterior, transmediastinal opening was readily shown by examination of human post-mortem material. This operation has been successfully performed on 4 patients.

lime salts was first detected in these patients on the 9th and 14th days of therapy, respectively. Not only the early date at which deposition could be detected but the amount of deposition in a given time compared favorably with that obtained with cod-liver oil. In Case 1 the patient received egg yolk during the latter part of the experiment, but this was not the cause of the early healing, for it was added to the diet only after healing had already begun. In Case 2 as much infection was present throughout the control period when there was no healing as during the first 2 weeks of therapy when healing occurred. It should be noted that both patients gained in weight during the periods in which the rickets was healing.

The serum analyses in both patients showed a lowering of the total calcium and a rise in the phosphate, and subsequently in Case 1 a rise in both. In this respect the babies reacted similarly to the rats. When the calcium was at the lowest point it was feared that tetany would supervene, yet it was never manifest by either a positive Chvostek's sign or convulsions. Repeated tests of the irritability to galvanic current were made, and it was demonstrated that latent tetany also was absent. It is interesting that the product of serum calcium and inorganic serum phosphorus was not high at the time deposition of lime salts was progressing. This fact, taken with the low calculated calcium ion concentration, indicates that the mechanism of calcification is not completely de-

scribed in either of these terms. The phosphatase content of the serum of both babies remained high throughout the period of observation compared with the normal range of 5 or 10 units by our modified Bodansky method. It is well known that high values may persist after other evidences of rachitic activity have disappeared, and may be found three to six months after adequate treatment. A return to normal during the short period of this study was not to be expected.

#### CONCLUSIONS

The evidence from the 2 cases reported indicates that mixtures of citric acid and sodium citrate induce healing in infantile rickets. This new form of therapy not only offers an adjunct to accepted measures for the treatment of infantile rickets, but also may have application to other types of disorders of calcium and phosphorus metabolism.

5,030,000, a white-cell count of 10,900 and a hemoglobin of 11.9 gm per 100 cc. Roentgenograms showed considerable decalcification, a widened uncalcified zone at the ends of the diaphyses, slight lipping of the epiphyseal margins and subperiosteal new bone along the shafts of the long bones. There was considerable diffuse flocculent peribronchial congestion.

The patient was placed on a non irradiated evaporated milk formula and given 50 mg of ascorbic acid per day but no vitamin D. After 15 days of this control period in which there was no evidence of beginning healing of the rickets (Table 2), the citric acid-sodium citrate mixture

initiated and was progressing. However, both the roentgenograms and the concentrations of serum calcium and inorganic phosphorus showed that healing was not complete when the experimental study was interrupted.

#### DISCUSSION

The order of magnitude of the citrate dosage is readily reduced to familiar terms by stating that the amount of citrate given each patient daily corresponded approximately to that contained in five or six large oranges.

Citrate mixture started on 16th day

described in Case 1 was started. The mixture was given daily in the formula from the 16th to the 41st day. The patient's upper respiratory infection continued about as at entry until the 14th day, when the temperature rose to 103°F, returning to normal in 2 days, again rising to 102.5°F on the 21st day, to drop the following day to within normal limits. From then until the 39th day he did well, and gained in weight from 16.5 to 17.3 pounds. On the 39th day the temperature rose to 104°F. At this time there was an acute right otitis media but no other signs of extension of the upper respiratory infection. Roentgenograms of the chest showed that the peribronchial congestion had markedly improved. Two days later the patient showed definite signs of pneumonia, the citrate therapy was discontinued and oil of percomorphum was added to the medication. This addition of vitamin D

In the experiments with rats,<sup>1</sup> citric acid in excess of sodium citrate was found more effective than the mixture used for these patients. The present proportions were used in order to avoid curdling of the milk. Subsequently it has been found that a more acid mixture, even as much as two parts molar acid to one part molar salt, is readily taken by patients, and it seems advisable that an acid mixture should be used.

The findings given in Tables 1 and 2 indicate clearly that by x-ray evidence healing had taken place during the administration of citrates and without vitamin D therapy. The deposition of

labile component (thiamin) has been regarded as the "anti-neuritic" or "anti-beriberi" factor, because it will cure in animals a disease which in some respects resembles human beriberi

Beriberi is a disease endemic in those parts of the world where milled rice is the staple cereal. Its first symptoms are loss of appetite and muscular weakness. Thereafter cardiovascular and neurologic signs develop and, according to which predominates, the disease has been differentiated into "wet" and "dry" types. The former probably represents the more acute and complete deficiency. Both the cardiovascular<sup>11</sup> and neurologic<sup>12</sup> manifestations of beriberi have recently been recognized in this country, occurring in cases of chronic alcoholism and occasionally in other subjects whose diet has been grossly abnormal. For further descriptions of these manifestations the reader is referred elsewhere.<sup>11, 14</sup> Briefly stated, the cardiovascular changes include edema, peripheral vasodilatation, tachycardia, cardiac enlargement and a liability to sudden circulatory collapse. The neurologic changes are those of the multiple sensory and motor neuritis formerly described as alcoholic polyneuritis, which has now been shown to be primarily due to nutritional deficiency rather than to the toxic effects of alcohol.<sup>15</sup>

It has long been recognized that beriberi can be cured by the administration of substances rich in vitamin B complex, but until very recently pure thiamin has not been obtained in amounts sufficient for clinical trial, and for this reason it has been impossible to determine with certainty the part played by thiamin deficiency in the development of the characteristic features of the disease. It now appears certain that the cardiovascular manifestations are a direct effect of thiamin deficiency, since administration of this vitamin complex results in most dramatic cures.<sup>11, 14</sup> It is less easy, however, to establish the etiologic relation of thiamin deficiency to the development of the neurologic changes. When the latter have progressed to the point of definite demyelination, recovery is necessarily slow, and so any therapeutic test is a relatively unreliable criterion of etiology, particularly since the administration of thiamin frequently improves the appetite and the consequent increase in food consumption presents the possibility that other dietary factors may contribute to the therapeutic response. However, there have been encouraging reports of definite improvement following the administration of thiamin in cases of alcoholic polyneuritis.<sup>17</sup> There is also evidence that the neurologic changes in alcoholism are liable to arise when the thiamin intake becomes theoretically inadequate.<sup>18</sup> In connection with this ob-

servation it must be emphasized that lack of thiamin may be associated with deficiency of other factors, as is illustrated by the fact that the onset of nutritional macrocytic anemia which is clearly not due to vitamin B<sub>12</sub> deficiency may coincide with the time when the thiamin intake becomes inadequate.<sup>19</sup>

Alcoholic polyneuritis is by no means the only type of nutritional polyneuritis seen in this country. Other conditions associated with a poor diet or gastrointestinal disorders may be accompanied by similar neurologic changes, and may well have the same etiology. It has been reported that the pain and numbness in pellagra may be relieved by thiamin.<sup>20</sup> The polyneuritis of pregnancy may respond to dietary supplements rich in vitamin B complex.<sup>21</sup> There have been many reports suggesting that thiamin deficiency may be responsible for the neuritis associated with diabetes, Korsakoff's psychosis, ulcerative colitis, gastric lesions and other conditions, but more work appears to be necessary before these theories can be accepted with certainty. It has also been suggested that some cases of Landry's paralysis may in reality be a form of beriberi.<sup>22</sup> The changes in the spinal cord which occur in pernicious anemia are probably not an effect of thiamin deficiency,<sup>23</sup> and this may also be true of similar changes in pellagra, sprue, celiac disease and beriberi. It is improbable that thiamin deficiency plays any part in the development of the other manifestations with which it is frequently associated in this country, such as anemia, pellagrous dermatitis, glossitis, achlorhydria and other gastrointestinal disturbances.

In conclusion, the present evidence suggests that thiamin deficiency is a factor, but not necessarily the only one, concerned in the development of nutritional polyneuritis. The appearance of polyneuritis in patients whose food intake is poor is, however, presumptive evidence of the existence of associated thiamin deficiency.

### Diagnosis

The diagnosis of thiamin deficiency at present depends on the clinical findings mentioned above and on the response of appropriate therapy. Several laboratory methods based on tests for the vitamin in blood and urine have been proposed, but none are as yet sufficiently well established to be used for routine purposes.

### Assay and Units

At present the only available method for estimating thiamin in foods is by feeding tests in animals. It has been usual to express the results of such tests in various arbitrary units, but now that pure thiamin is available as a standard of compari-

## REPORT ON MEDICAL PROGRESS

## THE WATER-SOLUBLE VITAMINS\*

ARNOLD P MEIKLEJOHN, B M †

BOSTON

## THE VITAMIN B COMPLEX

RECENT years have witnessed a great advance in knowledge of the chemical structure and physiological action of several components of the vitamin B complex. Three members of this complex are now chemically identified and have been given definitive names. The name thiamin has been recently proposed for vitamin B<sub>1</sub>, "to emphasize that this factor is a definite chemical entity distinct from all other substances."<sup>1</sup> Riboflavin has been identified as one of the agents responsible for the activity formerly attributed to the hypothetical vitamin B<sub>2</sub> (or G). Nicotinic acid is now established as a most important factor in the prevention of pellagra, and is responsible for at least the greater part of the activity which was once attributed to the P-P (pellagra-preventive) factor. It is to be hoped that future chemical identification of other vitamins will lead to the gradual adoption of such specific names, in place of the present confusing system of nomenclature by arbitrary letters and numbers.

THIAMIN‡ (VITAMIN B<sub>1</sub>)*Chemistry*

Thiamin hydrochloride is a white, crystalline substance readily soluble in water, having the formula  $C_{12}H_{17}N_4OSClHCl$ . It is easily destroyed by heat, particularly in alkaline solution. It can be synthesized on a commercial scale, and the synthetic product is now available for therapeutic purposes.

*Physiology*

Recent work has progressed far toward providing an understanding of the part played by thiamin in the metabolism of the body. There is now no doubt that it is an essential factor in the enzyme systems concerned with carbohydrate metabolism. Thiamin deficiency both in man<sup>3</sup> and animals<sup>4</sup> may result in an accumulation of pyruvic acid ( $CH_3CO COOH$ ) in the blood. This substance

is a product of glycogen breakdown, and it has been shown that thiamin is capable of catalyzing the oxidative removal of pyruvic acid from the tissues of animals deficient in this vitamin.<sup>5</sup> The diphosphate of thiamin has lately been identified as the co-enzyme activating yeast carboxylase which removes carbon dioxide from pyruvic acid, converting it to acetaldehyde ( $CH_3CHO$ ).<sup>6</sup> However, it has not yet been shown with certainty that it is precisely this reaction with which thiamin is normally concerned in the body. It is possible that thiamin may play a part in several other fundamental metabolic processes, including the conversion of carbohydrates to fat.<sup>7</sup>

*Animal Pathology*

Animals fed on a thiamin-free diet lose their appetite, become thin and after several weeks develop a severe disturbance of the nervous system characterized by opisthotonos and inco-ordination. This disturbance is not the exact counterpart of the human disease beriberi, since it is evidently due to disordered metabolism of the nervous system rather than to anatomic lesions in the peripheral nerves. This is proved by the fact that the condition is dramatically cured within a few hours by the administration of pure thiamin. It is reasonable to suppose that the course of complete thiamin deficiency is too rapid to allow time for the development of definite anatomic changes in the nerves, but that such changes might result from chronic, though partial, deficiency of thiamin. This, however, is difficult to prove experimentally, since it is impossible to maintain thiamin-deficient animals in a state of good general nutrition on account of their anorexia, and degeneration of nerves can occur as a result of simple starvation.<sup>8</sup> True polyneuritis can be produced by partial deficiency of the entire vitamin B complex,<sup>9</sup> but also by diets adequate in thiamin and lacking only the other factors in the complex.<sup>10</sup> It seems clear, therefore, that thiamin deficiency is not the only etiologic factor in the production of nutritional polyneuritis in animals.

*Human Pathology*

Ever since the first differentiation of the vitamin B complex into more than one component, the heat

From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard), Boston City Hospital, and the Department of Medicine, Harvard Medical School.

†Francis Weld Peabody Fellow, Harvard Medical School, assistant in medicine, Second and Fourth Medical Services (Harvard), Boston City Hospital.

‡For additional information the reader is particularly referred to Williams and Spies's book on thiamin.<sup>2</sup>

membered that thiamin deficiency rarely occurs without associated deficiency of other factors of the vitamin B complex, and, as pointed out above, these associated deficiencies may perhaps contribute to the development of polyneuritis. For this reason the best therapeutic results are not likely to be obtained from the administration of thiamin alone. At the present time there is no preparation suitable for parenteral administration of the entire vitamin B complex. In cases where intestinal absorption is likely to be grossly impaired the need may be partly provided for by the injection of liver extract and nicotinic acid as well as thiamin. In most cases, however, oral administration of vitamin B complex is entirely satisfactory. This is most easily provided by powdered brewer's yeast. Thirty to 90 gm daily is a suitable therapeutic dose, taken in milk or warm salted water. The administration of yeast by mouth is probably sufficient treatment for most cases of mild neuritis associated with alcoholism and other nutritional disturbances. It is useful in the prevention of polyneuritis in cases of hyperemesis gravidarum, and is also worth a trial in diabetic and post-infectious neuritis. In the absence of certain knowledge of the etiology of Korsakoff's psychosis it would seem advisable to administer large doses of all the components of the vitamin B group in the form of thiamin, nicotinic acid and liver extract by injection, and brewer's yeast by mouth. It should be remembered that patients with advanced neuritis and definite neurologic changes inevitably recover very slowly and often incompletely. This calls for perseverance in treatment in spite of only gradual improvement. Anorexia in the absence of other definite findings may occasionally be due to vitamin B deficiency, and its treatment may reasonably include the oral administration of yeast. This is particularly true in cases of underweight children with poor appetite. Three teaspoonfuls daily of autolyzed yeast is recommended as a suitable dose.

#### NICOTINIC ACID

Nicotinic acid has been familiar to organic chemists for many years, but it was not definitely recognized as a factor in the vitamin B complex until the end of 1937. It is a white, crystalline, heat-stable, water-soluble, easily synthesized substance with the simple formula  $C_6H_4N \text{ COOH}$ .

#### Physiology

Prior to its recognition as a vitamin, nicotinic acid was identified, in the form of its amide, as an essential constituent of an important enzyme system. Codehydrogenase (cozymase) is composed of nicotinamide, ribose, phosphoric acid and adenine. This compound has been shown to be cap-

able of activating dehydrogenases, which are an important group of enzymes concerned with the oxidation of many organic molecules in the tissues. It thus appears that nicotinamide is an important factor in normal tissue oxidation.

In 1937 it was discovered that nicotinic acid will cure blacktongue, a deficiency disease of dogs analogous to pellagra.<sup>27</sup>

#### Human Pathology

Space does not permit any description of pellagra. For a full account of this disease the reader is referred to an excellent review on the subject.<sup>28</sup>

#### Sources

There has not yet been time to determine with certainty the distribution of nicotinic acid in foods, but judging by what was previously known of pellagra-preventing diets it must be present in physiologically active amounts in those foods which are also good sources of thiamin. It is certainly present in yeast and crude liver extract.

#### Therapy

It now seems evident that nicotinic acid is a specific curative agent for many of the clinical manifestations of both alcoholic and endemic pellagra.<sup>29-31</sup> Thus the mental symptoms, diarrhea, mucous-membrane lesions and the erythematous element of the dermatitis are all dramatically cured by nicotinic acid therapy. The neurologic manifestations, however, are apparently not affected.

The most effective dose of nicotinic acid has not yet been determined. The daily oral administration of 500 mg in five divided doses has been recommended as usually effective. It has also been given intravenously in doses of 10 mg five times daily in sterile saline.<sup>32</sup> The oral and parenteral administration of nicotinic acid is often accompanied by tingling sensations, increased gastric motility and dilatation of peripheral blood vessels, which suggests that larger doses than those recommended above might result in further undesirable reactions.

Since it seems probable that nicotinic acid therapy will leave unaffected at least some of the manifestations frequently associated with pellagra, it seems advisable to use nicotinic acid as an additional therapeutic weapon rather than as a substitute for the former treatment by good diet, yeast and liver extract,<sup>33</sup> though probably the doses of these latter need not be so large as formerly.

#### OTHER FACTORS IN THE VITAMIN B COMPLEX

The other factors in the vitamin B complex will not be discussed in detail here, since at pres-

son it is obviously preferable to express vitamin B<sub>1</sub> potency in terms of pure crystalline thiamin. Unfortunately there are difficulties in converting the units formerly employed into terms of pure thiamin. The best compromise value at the present is probably that one international unit equals 3.3 micrograms of thiamin chloride. For discussion of other units formerly employed the reader is referred elsewhere.<sup>2</sup>

### Sources

Thiamin is present in a great variety of foods, but no one article is a particularly potent source. The concentration of thiamin in most foods is about one part in a million. Bio-assay is at present the only available method of estimating thiamin in foodstuffs, and owing to the disparity of results obtained by different types of feeding tests the thiamin content of different foods can be stated only in very rough terms. Some of the richer sources of the vitamin and their approximate thiamin content are given below.\*

	mg
One cup of milk (250 cc)	0.1
One helping of beef (100 gm)	0.05
One helping of pork or ham (100 gm)	0.3
One helping of liver, kidney or heart (100 gm)	0.2
One egg	0.05
One helping of most vegetables (100 gm)	0.05-0.1
One orange or other fruit of similar size (120 gm)	0.06
30 peanuts (30 gm)	0.24
One slice of white bread (25 gm)	0.01
One slice of whole wheat bread (25 gm)	0.1

It will be seen from these figures that pork, ham, liver and peanuts are unusually good sources of the vitamin, and that whole-wheat bread is a distinctly better source than white bread. Dried brewer's yeast is a very potent source of thiamin, and usually contains about 0.1 mg per gram.

The thiamin content of the food may be greatly influenced by the method of cooking. Though fairly stable to heat in acid solution, in the presence of alkali (as when sodium bicarbonate is added to preserve the color of vegetables) it is soon destroyed at the temperature of boiling water. The process of baking and the use of baking powder are both liable to lead to considerable destruction of thiamin. Much of the vitamin may be dissolved and lost if fruits and vegetables are boiled in a large volume of water which is afterward discarded. In general it can be said that much of the thiamin in an ideal diet is provided by milk, meat, eggs, fruit and vegetables, and that if the supply of these more expensive foods is restricted it becomes increasingly important to provide whole-wheat bread and flour in place of refined cereals.

### Requirements

The thiamin requirements of an adult have been shown to be dependent on both weight and

caloric intake<sup>4</sup> and, perhaps more specifically, on the carbohydrate consumption.<sup>2</sup> Thus the minimum requirement of a man weighing one hundred and forty pounds consuming 2000 calories daily is probably about 0.5 mg, while a man of two hundred pounds weight consuming 3000 calories may require at least twice this amount. This fact may explain why thiamin deficiency is liable to arise in alcoholic subjects whose consumption of foods rich in thiamin is frequently low, while their caloric intake (in the form of alcohol) is high.<sup>18</sup> It may also explain why signs of thiamin deficiency are rare in cases of general inanition with a reduced intake of both thiamin and total calories. It further indicates that thiamin deficiency is particularly liable to arise in patients whose metabolic rate and caloric consumption are raised, as in hyperthyroidism.<sup>25</sup>

The present evidence suggests that a safe optimum allowance for an adult is between 1 and 2 mg of thiamin daily. It is probably particularly important to maintain an optimum allowance during lactation. This is suggested by the frequency of infantile beriberi in those parts of the Orient where the usual diet is on the borderline of thiamin deficiency, and by the fact that the thiamin requirement of rats increases during lactation. Little is known of the thiamin requirements of childhood, but several reports of improved weight gain following the administration of substances rich in vitamin B<sub>20</sub> suggest that the diet of children in this country may sometimes fall short of the optimum in thiamin content. It is probably wise at the present time to assume that children require at least as much thiamin as adults.

### Therapy

Thiamin is specific in the cure of the cardiovascular manifestations of endemic and alcoholic beriberi.<sup>11, 16</sup> Because of the danger of sudden circulatory collapse, treatment of such cases should be started early, and thiamin should be given parenterally to ensure rapid action. Initial doses of 20 to 50 mg daily given intravenously, or perhaps better intramuscularly, are recommended. The dose may be reduced to 10 mg when definite improvement begins and so maintained until recovery is assured. These doses may in most cases be greater than is really necessary, however, there need be no fear of ill effects from using these amounts. Parenteral administration of thiamin is indicated in cases of nutritional polyneuritis in which there is evidence of gastrointestinal disturbance, and consequently the possibility of defective absorption of substances given by mouth. Daily doses of from 2 to 10 mg may be given, according to the severity of the case. It should be 10-

\* Adapted from Williams and Spies.<sup>2</sup>

nutrition, one above 50 mg is presumptive of excellent nutrition<sup>43</sup> Since both blood level and excretion may be influenced by recent dietary intake of the vitamin, it is considered that a more accurate estimate of the "degree of saturation" of the individual can be obtained by observing the effect of a test dose of the vitamin on the blood and urine levels There are many ways of carrying out this saturation test, and for further details the reader is referred to a recent review on the subject<sup>44</sup>

### Sources

Ascorbic acid occurs in most fresh vegetables The best sources are fruit and fruit juices One ounce of orange or lemon juice contains about 17 mg., an ounce of grapefruit juice 10 mg., of tomato juice 8 mg and of pineapple juice 5 mg One orange contains about 50 mg and half a grapefruit about 40 mg<sup>45 46</sup>

Ascorbic acid is very easily destroyed by oxidation This destruction is facilitated by heat, alkali, traces of copper and exposure to air These factors are of practical importance in cooking vegetables The water should be boiled (to drive off dissolved oxygen) before the vegetables are added It is advisable to use as little water as feasible, since the vitamin is freely soluble, and much may be lost when the water is discarded after boiling Sodium bicarbonate should never be added, the vessel used should have a lid, and should not be made of copper Modern methods of canning do not result in any great destruction of ascorbic acid if the reaction of the food is acid, as is the case with fruit juices Milk usually contains very little ascorbic acid by the time it reaches the consumer<sup>46</sup>

Pure synthetic ascorbic acid is available for therapeutic purposes, at a price that competes with orange juice as the cheapest way of supplying the vitamin

### Requirements<sup>45</sup>

There appears to be a great difference between the amount of ascorbic acid necessary to prevent scurvy and the amount required to keep the body saturated with vitamin Probably very few normal people are fully saturated, and it is extremely doubtful whether complete saturation is essential to perfect health At the same time it seems important that the degree of saturation be well above pre scorbutic level, in order to provide against any sudden increase in the demand for vitamin, as may happen, for instance, in infections

Infants probably require 5 to 15 mg a day to prevent the development of scurvy A daily dose of 20 to 50 mg should ensure a liberal supply

This amount is usually provided in the breast milk of a well-nourished mother, but even so, some additional vitamin may increase the margin of safety in breast-fed babies, and should certainly be given to bottle-fed babies A recommended procedure is to start with 1 teaspoonful of orange juice daily, and increase this gradually to 2 oz (30 mg of ascorbic acid) by the third month

The minimum daily requirement of children is probably about 20 mg To obtain complete saturation as much as 120 mg may be necessary Fifty milligrams is probably a sufficient "safety" allowance, the amount contained in one orange The minimum daily requirement in adults is about 30 mg, the safe allowance about 60 mg In pregnancy this amount should be doubled

There is good evidence that ascorbic acid is utilized with abnormal rapidity in a variety of infectious conditions<sup>47</sup> In rheumatic fever and tuberculosis, for instance, the blood level and excretion rates are frequently found to be low, despite an apparently adequate intake Although it is unlikely that ascorbic acid has any specific therapeutic value in infectious conditions, nevertheless it is well to ensure that such cases receive an ample supply

Patients receiving special diets, particularly for gastric ulcer, frequently receive inadequate amounts of ascorbic acid It is possible that this may be a factor in the causation of gastric hemorrhage, and it is therefore most important to insure an adequate intake of the vitamin in such cases<sup>48</sup>

### Treatment

In the treatment of scurvy large doses of the vitamin may be given (as much as 1 gm a day by mouth) But it is well to remember that toxic symptoms have been reported with very high dosages The vitamin may also be given parenterally, in the form of the monoethanolamine salt of ascorbic acid

Evidence of the beneficial effect of ascorbic acid in other conditions, as in hemorrhagic states other than scurvy, is not as yet sufficiently definite to require mention

### CONCLUSION

In this and a preceding article,<sup>49</sup> some account has been given of the principal properties of the vitamins, and of their use in the prevention and treatment of nutritional diseases Little mention has been made of the fundamental principles involved in questions of nutritional deficiency A few of these principles, which are fully discussed in a recent article,<sup>50</sup> may be summarized here as an appropriate conclusion

ent little is known of their importance in human nutrition. They have been recognized as indispensable to adequate nutrition in various species of animals. Future research may clarify their present complexity by chemical identification, and perhaps demonstrate that some of the factors at present described as separate entities are really identical. One of them, riboflavin, deserves mention, since it has been chemically identified and synthesized and has been shown to be the "prosthetic" or active group of Warburg's yellow enzyme, which plays an important part in normal tissue respiration. This fact suggests that it is probably an indispensable factor in human nutrition, and although no definite clinical manifestations have yet been attributed to deficiency of riboflavin and of the other remaining factors of the B complex, their importance in animal nutrition indicates that some, at least, are likely to be necessary for man. The distribution of riboflavin in foods closely follows that of thiamin.<sup>34</sup> All the known factors are present in yeast and some, at least, in liver. Nutritional macrocytic anemia has been noted in cases in which there is also evidence of thiamin deficiency,<sup>10, 35</sup> and a comparable anemia in monkeys has been shown to respond to yeast but not to thiamin or nicotinic acid.<sup>36</sup> In this connection it is noteworthy that the extrinsic factor of pernicious anemia has been thought to be part of the vitamin B complex.<sup>37</sup> As has been previously stated, a polyneuritis preventable by yeast may be produced in animals receiving an adequate intake of thiamin.<sup>10</sup> Finally, the spinal cord changes of beriberi, pellagra, pernicious anemia and sprue may be due to deficiency of one or more of the unidentified factors of the vitamin B complex. Demyelination of tracts in the spinal cord has been produced in pigs by a diet adequate in thiamin and riboflavin but deficient in other factors of the vitamin B complex.<sup>38</sup>

In conclusion, it may be said that besides thiamin and nicotinic acid there may yet be other factors in the vitamin B group which are almost equally important. For this reason, patients who show evidence of vitamin B group deficiency should be treated not only with synthetic thiamin or nicotinic acid, but also with liberal doses of the entire complex in the form of yeast, and with foods that are rich both in thiamin and in the factors associated with it.

#### ASCORBIC ACID (VITAMIN C)

##### Chemistry

Since vitamin C has been isolated and synthesized it has been given the names *cevitamic acid* and *l-ascorbic acid*, both of which are now in com-

mon use. It is a white, crystalline substance, freely soluble in water, with the simple formula  $C_6H_8O_6$ . It is very readily oxidized by the loss of two hydrogen atoms, to 2-dehydro ascorbic acid. This change can be reversed by reducing agents. But if oxidation proceeds further than dehydro-ascorbic acid the vitamin is irreversibly changed and its activity cannot be restored.

##### Physiology

Little is known of the part played by ascorbic acid in the chemistry of the body. The fact that it is capable of being reversibly oxidized and reduced has suggested that it may act as a respiratory enzyme in the tissues, but there is no direct evidence for this. The highest concentrations in the body are found in the suprarenal cortex and the pars intermedia of the pituitary gland.<sup>39</sup>

##### Pathology

The pathologic changes resulting from ascorbic acid deficiency are as follows. There is a marked diminution of intercellular substance, fibrous tissue is poor in collagen, the teeth lack dentine, the growing points of the long bones are deficient in osteoid tissue, which is replaced by calcified cartilage, giving a characteristic picture by x ray. The bone marrow is hypoplastic.<sup>40</sup>

Clinically, ascorbic acid deficiency results in scurvy, which is characterized by the following abnormalities. Hemorrhages are common, particularly under the periosteum, petechiae and perifollicular hemorrhages occur in the skin. The gums are swollen and boggy, and bleed easily. The teeth may be loose. Anemia is common, and in infants and children growth of the long bones is arrested.<sup>41</sup>

Vitamin C can be determined with comparative ease in blood plasma and urine. The estimation is reliable provided that certain precautions are taken in carrying it out. A large number of papers on the blood level and urinary excretion of ascorbic acid have recently been published. Many of the conclusions are still under discussion, but some important facts have emerged which now appear to be well established. The level of ascorbic acid in the blood plasma is very low in scurvy, usually less than 0.2 mg per cent, and frequently so low that it cannot be estimated. A fasting blood plasma level of 1.2 mg per cent or higher is evidence of excellent ascorbic acid nutrition. It appears that vitamin C is a threshold substance, and is excreted in the urine when the blood level exceeds 1.4 mg.<sup>42</sup> People who are apparently healthy show figures which range between 0.5 and 1.4 mg per cent. A twenty-four-hour urinary excretion of less than 10 mg is evidence of poor vitamin C

## CASE 25121

## PRESENTATION OF CASE

A fifty-six-year-old married Polish tailor was admitted with marked cyanosis of the face, neck and arms and gasping respirations.

Seven weeks before admission he entered an outside hospital. He had had chronic bronchitis for forty years, dyspnea on exertion for ten to fifteen years and occasional blood-streaked sputum for three to four years. For three and a half weeks before admission to the outside hospital he had had marked swelling of the face, neck and chest with coughing, inspiratory difficulty and wheezing. Physical examination revealed obvious respiratory distress, marked swelling of the face, neck and chest, lacrimation and edema of the conjunctivae, cyanosis of the face, ears, fingers and nail beds. The veins of the neck, chest and arms were distended and did not collapse. There were many telangiectatic areas over the chest and back. There were many crackling rales at the bases of both lungs and many respiratory wheezes, especially on the left. The heart was normal. The blood pressure was 110 systolic, 70 diastolic in both arms. Examination of the abdomen was negative. There was questionable clubbing of the fingers.

The urine examination was negative. The blood showed a red-cell count of 4,500,000 with 92 per cent hemoglobin and a white-cell count of 12,400 with 78 per cent polymorphonuclears, 7 per cent large lymphocytes, 14 per cent small lymphocytes and 1 per cent eosinophils. Blood Hinton and Wassermann tests were negative. The stools were normal except that one was guaiac positive. The sputum was pale green and contained much pus, many organisms, but no acid-fast bacilli. The venous pressure in the left arm was 425 mm, in the right leg 130 mm.

He remained in the outside hospital thirty-eight days. Respirations varied from 20 to 35 per minute. X-rays revealed a widened supra-aortic shadow, probably the vena cava. Biopsy of an axillary gland was negative. Bronchoscopy showed extensive bilateral bronchiectasis, marked congestion of the entire tracheobronchial tree, but no evidence of tumor. Lipiodol confirmed the pres-

ence of bronchiectasis, most marked at the left base. His right arm became more and more edematous, but this was eventually controlled with mercurial diuretics. After each diuretic his face and arm returned to almost normal size, though the swelling of his neck persisted. His respiratory distress was not materially aided. He lost 15 pounds in weight during the thirty-eight days chiefly because he became fatigued while trying to eat for more than a very short period of time. His last diuretic caused a loss of 3000 cc of fluid and he felt better than at any time during his hospital stay. He was discharged to his physician.

Nine days later he entered this hospital. Physical examination was similar to that on admission to the other hospital except that he was more severely affected with difficult, gasping respiration and cyanosis.

His temperature was 97°F, pulse 90, respirations 30.

X-ray films of the chest showed the right diaphragm to be unusually low, limited in excursion and irregular in outline. The left side of the diaphragm was not seen. The right lung was large and bright and there were many areas of rarefaction with thin walls, apparently blebs. There were many similar areas of rarefaction in the left lung, especially in the apex. Linear density was seen in both lungs apparently due to dilated blood vessels. There was homogeneous density at the left base rising to the seventh rib posteriorly and the gas bubble in the stomach was displaced downward below the twelfth rib. The heart and mediastinum were in normal position. Both lung roots were grossly enlarged. There was an oval mass just above the right main bronchus to the right of the mediastinum and in contact with the vena cava measuring 4 by 2.5 cm. The shadow of the vena cava appeared large above this point. The aorta was not dilated. The trachea was displaced slightly to the left just above the arch of the aorta. The carinal angle was widened and the main bronchi were indistinct. There was no evidence of disease in the bones.

Six and a half hours after entry the patient suddenly became cyanotic and had severe respiratory difficulty. An attempt was made to aspirate mucus from the larynx, and coramine was given subcutaneously and intravenously. After three minutes he stopped breathing and artificial respiration was begun. An apical heart beat was still present. A needle was introduced into the sixth right interspace in the anterior axillary line and about 400 cc of air was easily removed with a syringe, but on holding the connecting tube under water no bubbling was seen. At this time

1 Nutritional disease may arise not only from faulty diet, but also from defective absorption and utilization of various elements in the food

2 Dietary deficiency as seen in this country is rarely confined to deficiency of a single factor. It is therefore important that the physician should look for evidence of multiple deficiencies in any recognized case of nutritional disease

3 The administration of pure vitamin preparations is rarely sufficient for the complete cure of any deficiency disease, and should never be considered as a substitute for a good general diet

4 Most dietary deficiencies are best prevented by directing the inquiring patient to the grocer rather than the druggist

DR. KING So that there are probably nodes beneath the carina?

DR. HAMPTON Yes, that is a reasonable assumption I would like to see a little more compression of the main bronchi than you see here They do not seem to be very small

DR. KING The emphysema is probably not obstructive emphysema due to partial bronchial obstruction

DR. HAMPTON At any rate it is long-standing with bleb formation

DR. KING So we have no evidence that the mass presses on the bronchus from the outside?

DR. HAMPTON No

DR. KING Granted then that this is a lymph node, may it be enlarged because of infection secondary to chronic bronchiectasis? This would be an unusual finding and there is certainly no evidence of suppurative mediastinitis with a mediastinal abscess

DR. HAMPTON I should not think so

DR. KING Let us then discard the possibility of pulmonary infection with secondary mediastinitis and consider next the emphysema and its possible relation to the mediastinal obstruction Could emphysematous lungs press on the superior vena cava with resulting venous obstruction? Emphysema can do queer things and there are cases reported of choked disks supposedly caused by venous obstruction from emphysema In this case, however, I do not believe that we have the right to blame the whole picture on the emphysema and forget the mass which is apparently pressing on the vena cava

DR. TRACY B. MALLORY We have had one case with a fairly good upper mediastinal syndrome and nothing but emphysema to explain it

DR. KING But he did not have a mass and fluid to go with it

DR. MALLORY No

DR. KING We are then gradually being forced to consider the mass as a tumor and the tumor as responsible for the mediastinal obstruction, but there is one further possibility which must be at least mentioned, namely thrombosis of the superior vena cava secondary to long-standing pulmonary infection or in association with tumor Possible evidence of thrombosis with a fatal pulmonary embolus is shown in the last x-ray which was a postmortem film In this film there is a shadow in the left midlung field which was not present in the antemortem films The symptoms just before death could have been caused by pulmonary embolism although it is evident that the doctors in charge of the case believed that the sudden death was due to spontaneous pneumothorax

DR. HAMPTON I might say that I did not agree with the pathologist on this case The patient was said to have had a pneumothorax I cannot see it

DR. KING They put a needle in and took out 400 cc of air

DR. HAMPTON A bleb could cause what they found They could have put their needle directly into a bleb and obtained air under pressure

DR. KING They tapped in the anterior axillary line where many blebs were present I assume that they got the air from a bleb What about the shadow in the left lung field in the postmortem film?

DR. HAMPTON I thought it was due to an acute process like pneumonia

DR. KING You do not want to call it an infarct?

DR. HAMPTON No, sir

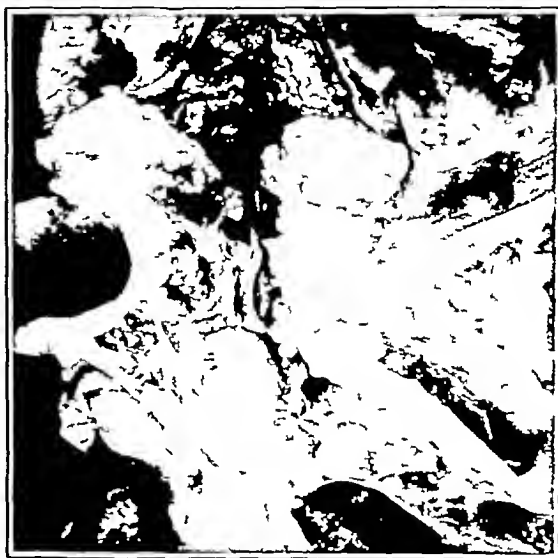

FIGURE 1 Small Primary Lesion of Bronchiogenic Carcinoma at Mouth of Tertiary Bronchus

DR. KING We have now lost what evidence there was for pulmonary embolism and infarct and have narrowed the diagnosis to tumor of a lymph node pressing on the superior vena cava There are a number of possibilities but it seems to me that the evidence is in favor of bronchiogenic carcinoma, probably primary in the left lower lobe with metastasis to the tracheobronchial lymph nodes on the right side of the trachea and beneath the bifurcation It is true that the bronchoscopy did not show any tumor in the main bronchi but in many instances the primary carcinoma is in the fine bronchi beyond reach of the bronchoscope

DR. FRANCIS M. RACKEMAN What about Hodgkin's disease?

the apical heart beat could no longer be heard and the pupils did not react to light. He died seven hours after admission.

#### DIFFERENTIAL DIAGNOSIS

DR DONALD KING In summary, we are dealing with a man of fifty-six who for forty years has had bronchitis, for fifteen years, dyspnea on exertion, for four years occasional blood-streaked sputum, and for ten weeks swelling of the face, neck and chest with cough, inspiratory difficulty and wheezing. There has been no fever. Physical examination showed crackling rales at the bases and some musical rales particularly on the left side. The venous pressure in the arms was high. The laboratory reported purulent sputum with no tubercle bacilli, and a negative Hinton. Bronchoscopy showed no intrabronchial tumor, but there is no note as to whether there was pressure from outside the bronchus. A biopsy of an axillary gland was negative.

There was obvious superior mediastinal obstruction and, besides this, x-ray of the lungs showed emphysema and large blebs. Lipiodol injection is said to have shown bronchiectasis. There was also fluid in the left pleural space and some masses in the region of the lung roots. We have then a chronic long-standing lung condition and superior mediastinal obstruction which has been present for about ten weeks. The first question is whether we can explain both findings by a single cause, and the decision must rest mainly on x-ray interpretation.

Let us consider first the two outstanding chronic infections, tuberculosis and syphilis. As you will see from examination of this x-ray film the appearance in the lung fields is not consistent with tuberculosis and the masses at the lung roots are not calcified tuberculous nodes. It is possible to have tuberculous mediastinitis due to breaking down of a tuberculous gland but there is no evidence here that such is the case. Syphilis must always be considered when there is mediastinal obstruction and one may have either syphilitic mediastinitis or pressure from aneurysm. In this case syphilis is ruled out by the negative Hinton and the x-ray which does not suggest aneurysm.

If you examine this film closely there is no question of the evidence of emphysematous blebs at the apices. Is there associated bronchiectasis? We have the statement that lipiodol injection did show dilatation of the bronchi but these films are not present for examination. The plain films which we do have are consistent with bronchiectasis. Is that not so, Dr Hampton?

DR AUBREY O HAMPTON It is not the type of picture I usually think of as due to bronchi-

ectasis, for the lobes involved are not reduced in size. They are blown up. The bronchi are dilated probably due to pulmonary fibrosis, but this is not the picture of the lung of bronchiectasis without emphysema. You can see honeycombed shadows throughout the lung, more marked at the right base which, if due to bronchiectasis, would indicate that there is more at the right base than elsewhere. The left base I cannot see because of a homogeneous shadow.

DR KING That is not collapsed left lower lobe with bronchiectasis?

DR HAMPTON No, it does not have the shape of a collapsed lobe. There could be collapse beneath this shadow which simulates fluid. The heart is not displaced to the right, if at all, it is toward the left, and that would indicate collapse of the left lower lobe with fluid or with a mass in the lung occupying about the same space as that amount of the fluid. This upward rise of the lateral margin of the shadow does look like fluid, but I think it would be difficult to rule out a mass in that area.

DR KING So all the help you can give me is that there is fluid at the left base?

DR HAMPTON With either collapse of the left lower lobe or tumor occupying the area of the left lower lobe.

DR KING He has large blebs at the apices. They do not show from a distance but are obvious on close examination.

DR HAMPTON They are even more obvious in the lateral view. There are huge ones anteriorly beneath the sternum. This oval mass to the right of the trachea and above the right main bronchus is definite and above it the shadow of the vena cava is definite. In a patient with emphysema the superior vena cava shadow should be narrow, but here it is wide.

DR KING We agree then that there is emphysema, emphysematous blebs, fluid at the left base and either collapse of the left lower lobe or tumor in this region. We must consider next the masses at the lung root, particularly the oval mass which Dr Hampton has mentioned. This mass looks to me like a lymph node. Do you agree with this?

DR HAMPTON Yes I think it is.

DR KING I would think so, and as far as I can tell, it is a node pressing on the superior vena cava.

DR HAMPTON Yes, the lower end of the superior vena cava.

DR KING Is that mass pressing on the right main bronchus?

DR HAMPTON I do not think so. You can see the bronchus fairly well and the carinal angle appears wide.

obstruction. A certain number of cases, and this one falls into the category, show multiple foci of pulmonary fibrosis. The lung, of course, is an elastic organ and has to fill the thoracic cavity. If some such process as organizing pneumonia, bronchiectasis or multiple infarcts destroys large areas of alveolar tissue and reduces them to minute fibrous scars the remaining lung tissue must dilate to fill their place, the volume of the thorax remaining constant. It seems to me that in a large proportion of cases of structural emphysema one can prove that a significant amount of lung tissue has been destroyed and then you get secondary dilatation of the remainder of the lung. That is not the whole story but I think it is a partial one.

DR WILLIAM BOYD. Do you not think that this case illustrates one of the great reasons for the recent increase in the incidence of bronchiogenic carcinoma? Do you think that thirty years ago a primary tumor would have been discovered?

DR MALLORY. I feel quite sure it would not. I think even ten years ago one might easily have passed this off as primary round-cell sarcoma of the mediastinum. Now we have become suspicious to the point where we believe bronchiogenic carcinoma through its metastases is the commonest cause of mediastinal tumor.

## CASE 25122

### PRESENTATION OF CASE

A sixteen-year-old Portuguese schoolboy was admitted complaining of swelling of the right lower leg.

The swelling gradually appeared without a previous story of trauma during the year before entry. It was not constant but would reach a size of 7.5 cm in width by 2.5 cm in thickness, last two to three days, then gradually regress only to reappear after three to four days. The swelling caused a dull pain, but tenderness could be elicited by pressure over the area when the swelling was absent. The area of enlargement did not become constant until about six months before admission at which time it began to grow more rapidly, the pain becoming constant. Three months later x-rays were taken, a diagnosis of sarcoma made, and amputation advised but refused. Two months before entry two doses of x-ray treatment were given which had no effect on the mass except that it became red and very tender. Three weeks prior to admission the pain became most severe, originating in the tumor and radiating down the medial aspect of the right leg. The pain was constant and made worse by exercise or pressure. At no time had there been

fever, chill or malaise. During the last three weeks he had had anorexia because of the pain. He believed that he had lost three to four pounds in weight during the last year. Both parents were living and well. He had two brothers in good health though one of them had a cleft palate. The past and family histories were otherwise non-contributory.

Physical examination showed a well-developed and nourished boy in obvious distress from a painful right leg. The general physical examination was negative except for the lesion on the leg. The blood pressure was 120 systolic, 80 diastolic. Over the anteromedial aspect of the right tibia in its middle third was a large, slightly fluctuant, red, slightly hot swelling measuring 10 by 10 by 5 cm. Slightly enlarged tender nodes were present in the right groin.

The temperature was 99.5°F., pulse 105, respirations 20.

The urine examination was negative. The blood showed a red-cell count of 5,250,000 with 75 per cent hemoglobin, and a white-cell count of 17,400 with 82 per cent polymorphonuclears, hematocrit 38 per cent. The corrected sedimentation rate was 0.45 mm per minute. The serum calcium was 10.35 mg per cent, phosphorus 4.8 mg per cent, phosphatase 17.92 units. A blood Hinton test was negative.

X-ray films showed destruction of the medullary portion of the right tibia at the junction of the middle and lower thirds over an area approximately 7.5 cm in length. The cortex was increased in thickness and showed new-bone formation arranged in "onion-skin" layers over this area. The cortex was broken through in one place over which there was a large soft tissue mass in which many bony spicules were present. X-ray films of the chest showed no evidence of metastases.

The patient felt well and his chart remained essentially normal during the first three days in the hospital. On the fourth day an operation was performed.

### DIFFERENTIAL DIAGNOSIS

DR. CLAUDE E. WELCH. I do not know whether we should see the x-rays first. I think Dr. Holmes might give away the diagnosis if it is what I think it is.

DR. GEORGE W. HOLMES. I know the answer.

DR. WELCH. Perhaps I had better talk first then. The problem here is to determine whether this is an inflammatory mass or tumor, our differential diagnosis between these two involving chronic osteomyelitis versus some form of bone tumor, of which I think we may exclude all types

DR KING One always has to think of it, of course I meant to speak of it. It is not the typical x-ray picture, is it Dr Hampton? I should doubt if we have to consider it. You do have to consider metastatic malignancy to these nodes. It might be from the stomach or several other sources, but there is no evidence of a primary source outside the chest.

DR HAMPTON No.

DR WYMAN RICHARDSON What about congenital cyst of the lung?

DR HAMPTON These cavities are multiple and thin walled and they look more like blebs than congenital cysts. They are in the location you would expect blebs. They contain no fluid. There is an associated big lung and low diaphragm and a lot of evidence of pulmonary fibrosis. I cannot see how cyst would be possible.

#### CLINICAL DIAGNOSES

Bronchiogenic carcinoma with mediastinal metastases

Emphysema

Rupture of emphysematous bleb with pneumothorax, right side

#### DR KING'S DIAGNOSES

Bronchiogenic carcinoma left lower lobe with metastases to the tracheobronchial lymph nodes

Pulmonary emphysema and emphysematous blebs

#### ANATOMICAL DIAGNOSES

Bronchiogenic carcinoma of left upper lobe with mediastinal metastases and obstruction of superior vena cava

Pulmonary emphysema

Pulmonary fibrosis, focal

Acute pleuritis with effusion

#### PATHOLOGICAL DISCUSSION

DR MALLORY The postmortem examination showed, as Dr Hampton has already indicated, one finding over which there will be some question. The thorax was punctured through a water seal and air bubbled out under pressure. This was interpreted as evidence of pneumothorax. I think x-ray evidence of pneumothorax is more reliable than such a procedure. If by postmortem x-ray they cannot find it I doubt if it is present, and what we did at autopsy was probably what was done during life—a puncture directly into an emphysematous bleb. Moreover the lung was not collapsed as one would expect with a positive pressure pneumothorax. The lung did show a

severe grade of emphysema which was quite diffuse. We found little or nothing at the left base except a considerable amount of fluid. The left lower lobe was slightly but not markedly atelectatic.

DR KING Was the fluid bloody or clear?

DR MALLORY It was yellow, slightly cloudy, not bloody. There were a number of masses in the mediastinum which appeared to be enlarged carinal lymph nodes and lymph nodes in the superior mediastinum, completely surrounding the lower end of the vena cava which was evidently obstructed by pressure from without. It was not invaded and contained no thrombi at the time of autopsy. A section of these nodes showed quite clearly that they were tumor, and no obvious primary source could be found at the time, but further dissection of the lungs after fixation showed a small tumor nodule about 1 cm in diameter in the left upper lobe fairly near to the most prominent gland that you see in the x-ray picture which microscopically is characteristic of primary bronchiogenic carcinoma.

DR HAMPTON How large did you say it was?

DR MALLORY A little over 1 cm in diameter. The cells are very small, very uniform, and correspond fairly closely with the so-called oat-cell carcinoma although the cells are rounder than is characteristic. There was no infarction or pulmonary embolus. There was a slight diffuse dilatation of the bronchi throughout the lower lobes but no marked bronchiectasis.

A PHYSICIAN How large was his heart?

DR MALLORY Normal. There was no cor pulmonale.

DR CHAMP LIONS We thought clinically that he had ruptured an emphysematous bleb when he had his acute episode.

DR HAMPTON There was no explanation of the sudden death?

DR RICHARDSON No embolus on the right side?

DR MALLORY No.

DR RICHARDSON Were you able to form any opinion as to the origin or cause of this emphysematous condition? It is a queer picture. This fellow started with symptoms at the age of sixteen according to the story.

DR MALLORY There are numerous theories of the origin of emphysema, none of which are very satisfactory. Very prolonged chronic bronchial infection is reported as one of the most frequent predisposing factors. It may or may not be associated with asthmatic paroxysms. It is usually assumed that the emphysema is produced by a process of bronchial obstruction. It is not at all clear, however, looking at the lungs of these individuals at postmortem, that there is bronchial

what they are by cutting into them Do you want to say anything about the gross appearance of these tumors?

DR MALLORY I should not want to commit myself very often on the gross appearance

DR TAYLOR In spite of amputation I should think that the prognosis was very poor I think that members of the staff who have not happened to see Dr Simmons's report of the results of sarcoma treatment at this hospital in a recent number of *Surgery, Gynecology and Obstetrics*\* would do very well to consult it, because he has presented his results in a very interesting fashion and also demonstrated that the prognosis in Ewing's tumor even with radical surgery is not very good

DR SIMMONS I have records of twenty-five personal cases of Ewing's that I have seen here and at the Huntington and other places Every one is dead There are a few in the registry without evidence of disease over five years but a very few

DR AUBREY O HAMPTON We had a five-year cure with radiation, but at the sixth year he had a recurrence

DR MALLORY What is the likelihood of developing pathological fracture if the lesion is untreated or treated only by radiation?

DR SIMMONS I have seen them occur That is all I can say

DR HOLMES I would like an opportunity to treat some of these cases in which the surgical results are bad I think one of the reasons we failed in the past is that we did not take into consideration the extent of the disease in the bone marrow The surgeon removes the whole bone. I should rather like to see a few cases treated that way The result should be better

#### CLINICAL DIAGNOSIS

Ewing's tumor (endothelioma) of right tibia

#### DR WELCH'S DIAGNOSIS

Ewing's tumor

Simmons, C. C. Bone sarcoma factors influencing the prognosis  
*Surg Gynec. & Obst.* 63 67 76 1939

#### ANATOMICAL DIAGNOSIS

Ewing's tumor of right tibia

#### PATHOLOGICAL DISCUSSION

DR MALLORY From the gross examination of the specimen we were not able to show that it extended any greater distance along the marrow cavity than the external swelling

DR TAYLOR Do you want to say anything about the difficulty of making frozen sections of these tumors?

DR MALLORY One is faced with considerable difficulty in that in many bone tumors a large amount of the tumor mass is going to be more or less calcified and it may prove quite impossible to cut a frozen section If one succeeds at all one has to cut such a thick section that the results are quite unsatisfactory The success of biopsy in these cases I think depends in about 90 per cent of the cases upon the surgeon If he will cut really into the tumor rather than giving you only the overlying capsule and if he will choose a portion of the tumor which is soft but which is not entirely necrotic there is no reason one should not be able to make an accurate frozen section diagnosis The selection of the material is of prime importance and that depends on the surgeon rather than the pathologist

DR TAYLOR Another difficulty in the matter of biopsy is that if you are dealing with a tumor in the region of a pathological fracture you may think that you have an ideal specimen for the pathologist only to find that you have given him only nonspecific reparative tissue

DR MALLORY It is quite possible for a malignant tumor to be surrounded by callus which may be difficult in gross to distinguish from the tumor One may get a completely false impression in that way

DR SIMMONS I think all the more about a remark Dr Ernest A Codman made here He said that when the clinician and the radiologist are in doubt the pathologist usually is too

DR MALLORY I would second that

except Ewing's and osteogenic sarcoma. In favor of osteomyelitis one might consider all the history and all the physical findings with two or three exceptions. The first and most important exception is the fact that the lesion is located in the central portion of the shaft of the tibia. The end of the tibia is the commonest spot for a chronic osteomyelitis of this type in contradistinction to a primary tumor. The increase in the white-cell count and slight fever, mean nothing in so far as the differential diagnosis of osteomyelitis and a primary tumor is concerned. When we consider the primary bone tumors of which Ewing's tumor and osteogenic sarcoma are the only two of importance in this case, we have a great deal in favor of Ewing's sarcoma. If we can trust the statement from the history that the swelling has been intermittent, we have one of the features of Ewing's tumor which is quite characteristic. Repeated small hemorrhages that occur in a very cellular tumor produce this change. They are not characteristic of osteogenic sarcoma which has much more stroma and none of these frequent fluctuations in size, nor of osteomyelitis. A Ewing's tumor should have responded to x-ray treatment if a sufficient amount had been given, we have no proof, however, that a therapeutic dose was administered. I do not think we have enough in that one statement to eliminate a Ewing's tumor. All the rest of the findings are in favor of Ewing's tumor.

Is there anything we can consider in favor of osteogenic sarcoma? The high white-cell count is unusual. I would expect in an osteogenic sarcoma with this much bone destruction and new bone formation that we ought to have an even higher serum phosphatase. The location is definitely in favor of Ewing's in contradistinction to osteogenic sarcoma, which more typically occurs in the head of the tibia. My preoperative diagnosis then would be a Ewing's tumor.

DR. HOLMES. I will continue the discussion by pointing out some of the characteristics of this lesion and the difference between osteogenic sarcoma and Ewing's tumor. I agree with Dr. Welch that we would be wasting our time to discuss the other possibilities. It is one of these two. It is a malignant tumor situated in the midportion of the shaft. It has characteristic ray formation, a soft tissue tumor, and has a considerable amount of onion-skin formation which is said to be commoner in Ewing's than in osteogenic sarcoma. It may occur in both. A localized tumor with marked ray formation is commoner in osteogenic sarcoma than in Ewing's. You would expect Ewing's tumor to extend farther up the shaft and have less of this marked ray formation. The

position of the tumor is commoner in Ewing's than osteogenic sarcoma. I think from x-ray alone the preponderance of evidence is in favor of Ewing's tumor, if you take the history into consideration, it is distinctly so. I might add that the fact that he had some unknown amount of x-ray treatment would not be of any importance in this discussion.

DR. TRACY B. MALLORY. Dr. Simmons, have you any comment?

DR. CHANNING C. SIMMONS. I know the answer. All I can say is that in Ewing's tumor you often get a slightly elevated white count and temperature. The situation is typical of Ewing's, but so far as the new bone formation goes it is unusual. We have cases in the museum upstairs, however, in which there was even more bone formation than that. In this situation, however, I should favor Ewing's tumor rather than osteogenic sarcoma.

DR. MALLORY. Do you think you can trust the phosphatase reaction?

DR. SIMMONS. With as much new bone formation as in this case I should expect a high phosphatase and you can get that in Ewing's. I saw a statement that onion-skin appearance did not occur in Ewing's until after they had had radiation. It was new to me, and I should like to ask Dr. Holmes about that.

DR. HOLMES. I should doubt that statement.

DR. ERNEST M. DALAND. I should like to add one thing. This boy was seen at Pondville before coming here where he is said to have received two x-ray treatments. That was not true. He had two x-ray photographs and never received any treatment. I tried to impress that on the resident staff when he was in the hospital this time but did not get it across apparently. At the time we saw his pictures they had an onion skin appearance without ray formation and for that reason we made the diagnosis of Ewing's tumor and advised amputation. That was refused and no treatment given.

DR. GRANTLEY W. TAYLOR. I operated on this boy and our preoperative diagnosis was Ewing's tumor. We explored the tumor which I think is the reasonable thing to do when you are confronted with the question of doing a very radical surgical procedure. An immediate frozen section revealed the nature of the lesion and, without removing the tourniquet, amputation was carried out above the level of the tourniquet. It was a thigh amputation. The gross pathological picture is said to be characteristic. I am not familiar enough with the gross appearance of these tumors to have a great deal of confidence in deciding

low men to be important individuals whether we will it or not, many more consider importance as an end in itself, and in achieving that end may do great good or great harm to those about us, a great many more are bent on being considered important, regardless of our deserts, and a not inconsiderable remainder either do not know what it is all about or derive a quiet satisfaction from being privates in an army composed mainly of top sergeants, if not of generals

Unfortunately for the cause of tolerance, man's progress has been competitive since first he took his club from the antlers in the front hall and strode forth in search of his quarry. By bringing home the largest buck, the comeliest mate or the most scalps, he demonstrated his superiority over his neighbors, and became a man of importance in their eyes and his own. Modern man, being ordinarily denied such opportunities, must content himself with collecting chairmanships, getting elected to a legislature or a board of selectmen, or bringing home a senator to dinner.

It is in the blood of all of us, that desire, quite separate from the profit motive, to be set apart from others, to be on a higher, or at least a different plane. The bandit glories to be designated as Public Enemy No. 1. According to his lights he has been set above his fellow men, he has made the front page. Many of the workers in any noble cause are there for the personal satisfaction they derive from the attached recognition of merit. The good that they do to the hospital or other charity is a satisfaction also, but of secondary importance.

It is usually quite harmless, our glory-seeking, doing no great damage to others and affording considerable satisfaction to ourselves if we are naïve enough to be satisfied with this plaything. It is when an overwhelming ambition becomes linked with a conscienceless brutality that we have the large scale destruction of human happiness that may be accomplished by the hand of the dictator.

Harm to ourselves results when the ambition for leadership is coupled with an incapacity for that form of self-expression. Then the ground is laid for the neuroses due to frustration or, if ambitions are fulfilled, to the consciousness of an

inability to discharge the obligations that we have brought on ourselves. Happiest is the individual who is unimportant except in those activities and to those persons whom he may claim for his own!

#### POSTPARTUM HEMORRHAGE DUE TO PARTIALLY ADHERENT PLACENTA

Mrs. A. C., a thirty-year-old primipara, at term and in active labor, was referred to the hospital on April 1, 1938, by her family physician.

The family history was essentially negative, and the patient's past history was entirely negative. Catamenia began at thirteen, were regular with a twenty-eight-day cycle and lasted four days without pain. Her last period was June 24, 1937, making her due for delivery March 31. Her pregnancy had been normal in every way.

Physical examination revealed an obese female. Her heart was not enlarged, there were no murmurs. Her lungs were clear and resonant, there were no rales. The blood pressure was 124 systolic, 84 diastolic. The fundus was three fingers below the ensiform, with vertex presenting, in ORA position and engaged. The fetal heart was heard in the right lower quadrant at the rate of 132.

Her labor was normal up to full dilatation, and the membranes ruptured eleven and a half hours after the onset of labor. Mid-forceps was done after two hours of full dilatation because of lack of progress, and an 8 pound, 8 ounce, female child was delivered in good condition. An extensive laceration on the left and the midline episiotomy were sutured with catgut. The placenta was not delivered.

There was a moderate amount of more or less continuous bleeding after the birth of the baby. An hour after the patient was delivered the pulse became rapid and of very poor quality, and then could not be felt. Her blood pressure could not be obtained. One thousand cubic centimeters of 5 per cent glucose administered intravenously resulted in improvement. A blood pressure of 70 systolic, 50 diastolic, and a pulse of poor quality with a rate of 128 were recorded. At this time

A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

## GRADUATE MEDICAL EDUCATION

THE recent meeting in Chicago of the Council on Medical Education and Hospitals of the American Medical Association records a definite forward step in the field of graduate medical education. For years the *Journal of the American Medical Association* has been publishing information about internships in hospitals throughout the country, and more recently it has published data concerning various residencies in approved hospitals. This information has been obtained in the course of the regular survey of hospitals which the Council has conducted for many years, but no attempt has been made to appraise these various residencies.

The Council has now developed a plan of co-operation with the American Board of Radiology for the fixing of standards of approved residencies, fellowships and graduate courses, and for the investigation of such facilities by the staff of the

Council. Both organizations will co-operate in the appraisal of these graduate opportunities, and much benefit should result. It is probable that similar co-operative studies will be arranged with the other specialty boards.

There are many indications of a greater interest in graduate medical education. The arrangement at Tufts College Medical School and Boston Dispensary whereby the physicians of New England can obtain postgraduate instruction has filled a very definite need. The survey now being undertaken by the Commission on Graduate Medical Education will result in valuable information about many phases of graduate study. And this co-operative investigation by the Council and the specialty boards will make available for physicians detailed information about the opportunities for graduate training. Until the various facilities have been thoroughly surveyed and adequate opportunity afforded to comply with the standards which may be adopted, it would seem more advisable to publish a graded list of all institutions offering opportunities, as was done with medical schools at first, rather than to give merely an approved list of those institutions meeting the standards. Then after a few years have elapsed and the standards have become clarified and generally accepted, an approved list can be published. Where standards have varied greatly, or perhaps better, where definite standards have not existed, a gradual approach to the solution of the problem could well be taken, and an opportunity provided for the dissemination of knowledge about new standards and the development of means of fulfilling them. By such a program it seems reasonable to expect that this new co-operative appraisal of facilities for graduate medical study will accomplish far-reaching effects on future medical practice.

## ON THE IMPORTANCE OF BEING UNIMPORTANT

THE *March of Time*, as it flashes across the screen, reveals largely the activities of individuals sufficiently important to be flashed across the screen in the *March of Time*. A few of us on earth are sincerely and humbly valuable enough to our tel-

there was no bleeding, and because of the patient's condition and the absence of hemorrhage, it was decided that the uterus should not be invaded.

During the next several hours she was given 4000 cc of 5 per cent glucose and 800 cc of blood. Her pulse varied from time to time, sometimes it was not palpable at the wrist, and when obtained, had a rate as rapid as 150. At the end of seven hours her condition was much improved. Her blood pressure had risen to 130 systolic, 70 diastolic, but the pulse rate was still 150. It was decided that her condition then admitted exploration of the uterus. Under light nitrous oxide and oxygen anesthesia an aseptic vaginal examination was performed. The cervix admitted two fingers but was easily dilated to admit the hand. The placenta was found to be slightly adherent for about two thirds of its area. A line of cleavage was easily obtained, and the placenta completely peeled off. The uterus was not packed. Oxytocics were given, and there was no more bleeding. The patient ran a septic temperature for ten days and was discharged on the seventeenth day. The red-blood-cell count on the tenth day was 3,150,000 and the hemoglobin 50 per cent.

*Comment* Cases with a partially adherent placenta oftentimes bleed, over a continued period of time, much more than one appreciates. There is never any tremendous hemorrhage, but there is a great deal of more or less continuous bleeding until finally the patient goes into deep shock.

This patient's condition was so poor that the procrastination adopted proved to be an intelligent procedure. There was no more bleeding. The treatment for shock and the replacement of human blood improved the patient's condition so that exploration of the uterus could be done safely.

The removal of such placentas must be accomplished under the strictest asepsis. No other condition of obstetrics carries with it as great a risk of infection as does the removal of an adherent or partially adherent placenta. The sepsis in this case, fortunately not too severe, was treated purely conservatively. It is possible that intravenous injection of 2 minims of posterior pituitary extract might have resulted in the separation of this placenta, thereby doing away with the possibility of infection.

#### ANNUAL MEETING OF THE MASSACHUSETTS MEDICAL SOCIETY

The annual meeting of the Massachusetts Medical Society will be held at Worcester on Tuesday, Wednesday and Thursday, June 6, 7 and 8 at the Worcester Memorial Auditorium. The annual dinner will be held on Wednesday at the Hotel Bancroft.

There is to be a definite change in the program this year in that the section meetings will be held consecutively. No two meetings will be held at the same time.

A combined clinical meeting is scheduled for Wednesday morning at which four prominent speakers will be present. In the afternoon a series of round-table discussions will be open to all members of the Society.

#### LEGISLATIVE NOTES

##### EXPLANATION OF THE TABULATION OF THE POSTCARD BALLOT ON THE OSTEOPATHIC BILLS AND THE ANNUAL REGISTRATION BILL

The ballots were sorted according to towns and counted through March 18 morning mail. Office addresses were given in many instances. In the case of all persons who gave Boston addresses their residences were checked by reference to the latest Directory of the Massachusetts Medical Society dated February 15, 1938, and they were allocated to the town of residence rather than the town of office. Due to recent changes subsequent to the listing there may be a very few inaccuracies in this sorting, but it is believed that any errors derived from this cause would not be systematic and would not affect the results of the ballots. The Boston cards were sorted according to districts. The cards under Boston proper contain all addresses from the Back Bay, North End, South End and West End. All other districts of Boston are sorted according to the name of the district.

The tabulation giving the vote by towns on annual registration includes the affirmative, negative and blank votes on this question. No tabulation by towns was made in regard to the votes in favor of either of the osteopathic bills or the blank votes in regard to the osteopathic bills, since the sum of these items was such a very small per cent of the total vote and there was no region from which there was any appreciable number of such votes.

TABLE 1 *Vote on Osteopathic Bills*

Franklin, Charles Eliot Ware Memorial Fellowship to Henry S. Fuller, 2M, of Washington, District of Columbia, George Cheyne Shattuck Memorial Fellowship to Bernard German, 3M, of Newark, New Jersey, James Jackson Cabot Fellowship and John Foster Award to Hubert W. Smith, 2M, of Dallas, Texas. John White Browne Scholarship to Franz J. Ingelfinger, M.D. 36, of Swampscott, Dr. William Hunter Workman Scholarships to Lewis Dexter, M.D. 36, of Cambridge, and Lewis W. Kane, 4M, of Woonsocket, Rhode Island.

Dr. Otakar J. Pollak has been appointed professor of bacteriology, pathology and immunology at the Middlesex University School of Medicine. He holds the degrees of Doctor of Medicine and Doctor of Science from Masaryk University where for four years he taught pathology. In Czechoslovakia he is licensed as a specialist and a sworn court expert in the fields of bacteriology, serology, pathology, histology, hematology, biochemistry, hormone research, assimilation and electrocardiography.

Other new members of the faculty of Middlesex University School of Medicine are Dr. Francis W. Hooper, of Westwood, a graduate of Harvard College and Boston University School of Medicine, as instructor in pediatrics; Dr. George Schwartz, of 311 Commonwealth Avenue, Boston, a graduate of Tufts College Medical School and associate member of the New England Dermatological Society, as instructor of dermatology; and Dr. Hyman Shrier, of Newton, a graduate of Tufts College Medical School and a member of the New England Obstetrical and Gynecological Society, as instructor in gynecology.

The Ring Sanatorium and Hospital has announced the appointment of Dr. Curtis T. Prout as medical director to succeed Dr. Hosea W. McAdoo.

## MAINE NEWS

The York County Medical Society, under the auspices of the Committee on Graduate Education, presented a most valuable and interesting panel discussion on pneumonia at a meeting held in Scarborough on January 4. The following physicians comprised the panel: chairman, Frederick T. Hill, Waterville, history and examination; T. E. Hardy, Waterville, pathology; Julius Gottlieb, Lewiston, x-ray diagnosis; Langdon T. Thaxter, Portland, cardiac complications; E. H. Drake, Portland, surgical complications; S. A. Cobb, Sanford, medical treatment; E. R. Blaisdell, Portland. This panel discussion was repeated at the meeting of the Kennebec County Medical Society in Waterville on February 16.

The regular monthly meeting of the Penobscot County Medical Association was held Tuesday, December 20, 1938. Guests of the association were Dr. W. H. Bunker, president of the Maine Medical Association, and Dr. Channing Frothingham, president of the Massachusetts Medical Society. Dr. Frothingham conducted a medical clinic at the Eastern Maine General Hospital during the afternoon.

Following dinner at the Bangor House at 7 p. m., a group of 61 interested physicians listened to the speakers of the evening. Dr. Bunker presented some of the problems which confront the Maine medical group, and his remarks elicited long and lively discussion from the floor. Dr. Frothingham chose for his subject "Economic Problems in Medicine, stressing especially the need for concerted and co-ordinated efforts by the medical profession to meet the challenge from the laity at the present time. Some proper form of insurance was advocated by the speaker.

## RÉSUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR JANUARY, 1939

DISEASES	JAN. 1939	JAN. 1938	FIVE YEAR AVERAGE*
Anterior poliomyelitis	1	0	1
Chickenpox	1433	2196	1532
Diphtheria	22	17	39
Dog bite	509	625	520
Dysentery bacillary	20	6	2
German measles	66	57	247
Gonorrhea	350	376	457
Lobar pneumonia	619	531	757
Measles	1955	566	2708
Meningococcus meningitis	5	3	9
Mumps	771	617	878
Paratyphoid B fever	0	1	0
Scarlet fever	797	1162	1051
Syphilis	700	433	434
Tuberculosis, pulmonary	292	267	283
Tuberculosis other forms	20	33	35
Typhoid fever	8	6	5
Undulant fever	8	2	3
Whooping cough	591	593	1144

Based on figures for preceding five years.

### RARE DISEASES

*Anterior poliomyelitis* was reported from Lynn, 1, total, 1.

*Anthrax* was reported from Ludlow, 1 total, 1.  
*Diphtheria* was reported from Beverly, 1, Boston, 2, Cambridge, 1, Foxboro, 1, Lawrence, 11, Lynn, 1, Methuen, 1, Peabody, 1, Woburn, 1, Worcester, 2, total, 22.

*Dysentery bacillary* was reported from Danvers, 12, Fall River, 1, Foxboro, 1, Holyoke, 1, Wellesley, 2, Wrentham, 3, total, 20.

*Infectious encephalitis* was reported from Foxboro, 1, Springfield, 1, total, 2.

*Malaria* was reported from Springfield, 1, total, 1.  
*Meningococcus meningitis* was reported from Arlington, 1, Belmont, 1, Cambridge, 1, Lexington, 1, West Auburn, 1, total, 5.

*Pfeiffer bacillus meningitis* was reported from Attleboro, 1, Brockton, 2, Salem, 1, total, 4.

*Septic sore throat* was reported from Beverly, 1, Boston, 3, Falmouth, 1, Fall River, 1, Gardner, 2, Lawrence, 3, total, 11.

*Tetanus* was reported from Fall River, 1, total, 1.  
*Trachoma* was reported from Cambridge, 1, Lawrence, 1, Malden, 1, total, 3.

*Trichinosis* was reported from Medford, 3, total, 3.  
*Typhoid fever* was reported from Acushnet, 1, Boston, 1, Greenfield, 1, Longmeadow, 1, Ludlow, 1, Milford, 1, Somerville, 1, Watertown, 1, total, 8.

*Undulant fever* was reported from Gardner, 1, Grafton, 1, Leominster, 1, Leverett, 1, Salem, 1, Sharon, 1, Townsend, 1, West Springfield, 1, total, 8.

Anterior poliomyelitis continued to show low incidence.

Measles, German measles, scarlet fever, chickenpox and diphtheria were reported below the five year average.

Pulmonary tuberculosis was reported at a record low figure for the second consecutive month.

Lobar pneumonia, whooping cough, mumps and meningococcus meningitis were reported below the five year average.

Tuberculosis (other forms) showed record low figures.  
Undulant fever was reported at a record high figure.  
Typhoid fever was reported above the five year average.  
Animal rabies showed record low incidence for the second consecutive month. Cases were reported from Bedford, Marblehead, and Wayland.

## MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning March 27

### BARNSTABLE

Sunday, April 2, at 4 00 p m, at the Cape Cod Hospital, Hyannis Subject—Cesarean Section, Analgesia Instructor Robert L DeNormandie Donald E Higgins, *Chairman*

### BERKSHIRE

Thursday, March 30, at 4 30 p m, at the House of Mercy Hospital, Pittsfield Subject—Syphilis Latent syphilis—diagnosis and treatment. Instructor Rudolph Jacoby Melvin H Walker, Jr, *Chairman*

### BRISTOL NORTH

Thursday, March 30, at 4 00 p m, at the Morton Hospital, Taunton Subject—Bleeding in the Third Trimester of Pregnancy Instructor Raymond S Titus Lester E Butler, *Chairman*

### BRISTOL SOUTH (Fall River Section)

Tuesday, March 28, at 4 00 p m, at the Union Hospital, Fall River Subject—The Control and Treatment of Respiratory Infections (This is to include the serological treatment of pneumonia in infants and children) Instructor Charles F McKhann Howard P Sawyer, *Chairman*

### FRANKLIN

Wednesday, March 29, at 8 00 p m., at the Franklin County Public Hospital, Greenfield Subject—Bright's Disease and Hypertension Evaluation of new therapy, diagnosis Instructor Robert S Palmer Halbert G Stetson, *Chairman*

### HAMPDEN

Thursday, March 30, at 4 00 p m, at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8 00 p m, in the Out patient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. Subject—The Indications and Contraindications for Removal of Tonsils and Adenoids Instructor Louis K Diamond. George L. Schadt, *Chairman*

### MIDDLESEX EAST

Tuesday, March 28, at 4 00 p m., at the Melrose Hospital (Colby Hall), Melrose. Subject—Heart Disease The treatment of "heart attacks or cardiovascular emergencies" Instructor Wilfrid J Comeau Walter H Flanders, *Chairman*

### MIDDLESEX NORTH

Thursday, March 30, at 4 30 p m., at St. John's Hospital, Lowell Subject—Anemia Modern methods in diagnosis and treatment of blood dyscrasias Instructor Chester S Keefer William S Lawler, *Chairman*

### MIDDLESEX SOUTH

Tuesday, March 28, at 4 30 p m, at the Cambridge Hospital, 330 Mt. Auburn Street, Cambridge. Subject—Medical Complications in Pregnancy Instructor James C Janney Alexander A Levi, *Chairman*

### SUFFOLK

Thursday, March 30, at 4 30 p m, in John Ware Hall, Boston Medical Library, 8 Fenway, Boston. Subject—Gonorrhea Modern treatment. Instructor Oscar F Cox, Jr Reginald Fitz, *Chairman*

## DEATHS

MacCALLUM—WALLACE P MacCALLUM, M.D., of 290 Common Street, Belmont, died March 9 He was in his sixty second year

Dr MacCallum received his degree from Jefferson Medical College of Philadelphia in 1904 He was a former member of the Massachusetts Medical Society

His widow, a son, a daughter and two sisters survive him

STEVENS—EDMUND H. STEVENS, M.D., of 1911 Massachusetts Avenue, Cambridge, died March 14 He was in his ninety fourth year

Born at Stanstead, Province of Quebec, he received his early education in Skowhegan, Maine, where his family had moved After his graduation from Dummer Academy he entered Harvard Medical School and received his degree in 1867

Dr Stevens was surgeon on the staff of the Cambridge Hospital for twenty five years, from which position he retired in 1911 devoting his time to general practice.

He was a fellow of the Massachusetts Medical Society, the American Medical Association and the American College of Surgeons, a member of the New England Surgical Society, the Boston Obstetrical Society and the Cambridge Medical Improvement Society

A son, Dr Horace P Stevens, a grandson and two grand daughters survive him

## NEW HAMPSHIRE MEDICAL SOCIETY

### DEATH

WEAVER—CHARLES A WEAVER, M.D., died in Manchester, New Hampshire, on March 6 He was born in Milford, July 2, 1855, and graduated from the University of Vermont in 1881 Dr Weaver practiced in Manchester and New Boston for more than fifty years and was affiliated with the State Board of Health for twenty years.

His memberships included the New Hampshire Medical Society and the American Medical Association His widow and a sister survive him

## MISCELLANY

### NOTES

Fourteen men have been granted traveling fellowships, fellowships and scholarships, totaling \$12,050, by the Harvard Medical School, it was recently announced at Harvard University These awards, for the coming academic year, are as follows William O Moseley, Jr, traveling fellowships to Samuel Lewis, M.D. '34, of Fitchburg, Richard B Pippitt, M.D. '37, of Port Jervis, New York, and Paul C Zamecnik, M.D. '36, of Cleveland, Ohio, Jeffrey Richardson Fellowship to Sinclair H Armstrong, Jr, M.D. '37, of New York, New York, DeLamar student research fellowships to Milton Elkin, M.D., of Dorchester, Edward S Miller, M.D., of Sioux City, Iowa, and Herbert R. Morgan, M.D., of Bell, California John Ware Memorial Fellowship to Bernard D Davis, M.D. of

## TYPE 14 THERAPEUTIC SERUM

Attention is called to the fact that the Department is now distributing serum for the treatment of pneumonias due to Type 14 in addition to those previously available without charge (Types 1, 2, 5, 7, and 8). This last addition is a rabbit serum and is not made by the Department's Antitoxin and Vaccine Laboratory but is purchased from a commercial manufacturer. Except when there is an unusual prevalence in a particular area of the State, this serum will be available only through the five laboratories noted on the accompanying list. The basic dose for infants is 40,000 units and for adults 100,000 units.

There is a considerable amount of evidence, much of which is unpublished, that serum treatment of Type 14 pneumonias will reduce both the fatality rate and the duration of illness. Pneumonia due to this type is most frequently encountered in infants and young children but is occasionally found in adults. Bullowa and Gleich<sup>1</sup> report that Type 14 was the etiologic agent in 218 cases (57 per cent) from a series of 2816 cases of pneumococcal pneumonia. When the 2816 cases were analyzed by age it was found that Type 14 was responsible for 20 per cent of all pneumococcal pneumonias in infants under two years of age, 14 per cent among children two to twelve years, and 3 per cent among adults. Among those in their series not treated by serum Type 14 pneumonia was most serious in adults (32 per cent fatal), quite serious in infants under two years (161 per cent fatal) and least serious in children two to twelve years (98 per cent fatal). In Heffron's series of 185 collected cases due to this type not treated with serum (quoted by Plummer<sup>2</sup>) there were 66 deaths, a fatality rate of 35.7 per cent.

## COMPONENTS OF POOLS OF DIAGNOSTIC SERUM

All laboratories are not prepared to identify pneumococci through Type 32 and some of them (when Types 1, 2, 3, 5, 7, 8, or 14 are not present) will be reporting a pneumococcus belonging to a particular group. The types included in each of the pools of diagnostic serum are given here for reference.

## Mixture A—Types 1, 2, and 7

B—	3, 4, 5, 6, and 8
C—	9, 12, 14, 15, and 17
D—	10, 11, 13, 20, 22, and 24
E—	16, 18, 19, 21, and 28
F—	23, 25, 27, 29, 31, and 32.

The pneumococci which cannot be identified completely by local laboratories are usually sent on to the State Bacteriological Laboratory for typing. However, if the physician plans to purchase commercial serum to treat a case, in order to save valuable time the sputum should be sent to the nearest local laboratory which is prepared to identify all types.

PAUL J. JAKMAU, M.D.,  
*Commissioner of Public Health*

State House  
Boston

## CORRESPONDENCE

### REGULATIONS RELATIVE TO TRANSFUSIONS

*To the Editor* At the last meeting of the Department of Public Health, on Tuesday, January 10, regulations were adopted relative to the use of blood or other tissues for purposes of transfusions, and so forth. These regulations were published in the *New England Journal of Medicine* (220:171, 1939). They were to become effective ninety days from date of passage. The date upon which they were to become effective was thus advanced in order that those who found the regulations to be unreasonable might call the fact to the Department's attention.

So many entirely reasonable requests for amendment have been received that the Department, at its meeting on March 14, voted to revoke the previously adopted regulations and to substitute the following therefor. These new regulations become effective on April 10.

PAUL J. JAKMAU, M.D.,  
*Commissioner of Public Health*

State House,  
Boston.

\* \* \*

### REGULATIONS RELATIVE TO THE USE OF BLOOD OR OTHER TISSUES FOR PURPOSES OF TRANSFUSION, ETC

(Under the provisions of the General Laws, Chapter 111, Section 6.)

#### INTERPRETATION AND DEFINITION OF WORDS AND TERMS

- 1 Donor Any person whose blood, unsterilized fraction of blood or tissue, is introduced into the body of another person by transfusion or otherwise.
- 2 Recipient Any person into whose body the blood, unsterilized fraction of blood or tissue of another person is introduced by transfusion or otherwise.
- 3 Dangerous disease Any disease which has been declared by the Department of Public Health to be dangerous to the public health and which is transmissible by the introduction of the blood, unsterilized fraction of blood or tissue of the donor, into the body of the recipient.
- 4 Withdrawal of blood or tissue The withdrawal of blood or tissue from the body of the donor, whether for immediate introduction into the body of the recipient, or for deferred introduction as, for example, of banked blood or serum.
- 5 Blood test A blood test for syphilis.

#### EXAMINATION OF DONOR

No person shall introduce the blood, or any unsterilized fraction of the blood or tissue, of any donor into the body of any recipient unless said donor has never had syphilis or malaria and is free from any dangerous disease, so far as such freedom from past and present infection can be determined by the following examinations and tests:

- 1 A carefully taken history as to past or present infection with syphilis or malaria, as to possible exposure to syphilis within the preceding two months, and as to the presence of symptoms of infection with any dangerous disease, and a careful physical examination which shall consist at least of an inspection of the skin from

head to feet for any rash or eruption, of the mouth for enanthem, of the external genitalia for any lesion or scar, and the recording of the body temperature, said history to be taken and said examination to be made, by a registered physician, immediately before the withdrawal of blood or tissue.

- 2 A blood test within thirty days prior to withdrawal of blood or tissue, provided that, in the case of emergency, if no previously blood tested donor is available and a rapid blood test cannot be made, said test may be omitted, but such omission and the reason therefor shall be made known to the recipient if possible, or to the recipient's guardian or nearest relative if available.
- 3 If the blood test hereinbefore required was made more than five days prior to the withdrawal of blood or tissue, or omitted because of emergency, a specimen of blood shall be collected at the time of withdrawal of blood or tissue, for subsequent testing for syphilis.

#### 4 Exceptions

If both donor and recipient are suffering from the same disease, the infection of said donor with that disease shall not prohibit the use of said donor's blood or fraction of blood or tissue for introduction into the body of the recipient.

Nothing in these regulations shall prohibit the therapeutic use of malaria.

#### EXAMINATION OF RECIPIENT

It shall be determined by a registered physician, before introduction of the blood, unsterilized fraction of blood or tissue, of a donor into the body of the recipient, whether or not said recipient has syphilis or any other dangerous disease, so far as it can be determined by a carefully taken history, a careful physical examination, and a blood test, except that in the case of emergency if a blood test cannot be performed, a specimen of blood shall be collected before the introduction of blood or tissue, for subsequent test for syphilis.

#### THE KEEPING OF RECORDS

The name, age, sex, color, marital status and address of both donor and recipient, the type of blood test performed on the donor, the results of the tests and examinations herein required, by whom performed, the date of withdrawal of blood or tissue and of its introduction into the body of the recipient, the name of the physician who introduced it, the omission of any blood test herein required and the reason therefor, shall be entered in the permanent records of the hospital, institution, clinic or physician under whose jurisdiction the introduction of blood or tissue was performed, and in such a manner that all the said data may be readily located by reference to the recipient's medical record.

#### PNEUMOCOCCUS-TYPING AND SERUM DISTRIBUTION SERVICE

*To the Editor* The accompanying list of laboratories for pneumococcus typing and serum distribution has been revised and includes all recent changes in their status. Two columns have been added to the form used in previous lists, one to show which types each laboratory is equipped to identify and the other to note from whom each laboratory usually accepts specimens.

Additions to and changes in this list are made from time to time. Due to the high cost of the serum the number of distributing stations is kept as low as possible. At present Type-I serum is easily available in all parts of the State and serums for certain higher types are available at strategic points throughout the State. The distribution of pneu-

mococcus-antibody solutions is restricted to those hospitals, institutions or agencies equipped to do pneumococcus typing and employing bacteriologists or laboratory technicians who have been approved by the Department of Public Health as to their familiarity with typing procedures

## NOTICES

### HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held on Tuesday, March 28, in the Peter Bent Brigham Hospital amphitheater (Shattuck Street entrance), at 8 15 p m.

#### PROGRAM

Presentation of cases

Primary Tumors of the Lung Dr Edward D Churchill.

Medical students and physicians are cordially invited to attend

ROBERT ZOLLINGER, M.D., *Secretary*

### COMBINED MEETING OF THE SUFFOLK DISTRICT MEDICAL SOCIETY AND NEW ENGLAND PEDIATRIC SOCIETY

There will be a combined meeting of the Suffolk District Medical Society and the New England Pediatric Society on Wednesday, March 29, at 8 15 p m., at the Boston Medical Library, 8 Fenway, Boston.

Dr Albert D Kaiser, of Rochester, New York, will speak on Significant Facts in the Tonsil Problem in Children. Dr Francis L. Welle will open the discussion

JOHN P. MONKS, M.D., *Secretary*  
Suffolk District Medical Society

JAMES M. BATY, M.D., *Secretary*,  
New England Pediatric Society

### FIRST ANNUAL REGIONAL CONVENTION OF THE ASSOCIATION OF MEDICAL STUDENTS

The first annual regional convention of the Association of Medical Students will be held at the Harvard Medical School, April 1, 2 and 3. Distribution of Medical Care has been selected as the general subject of the convention.

The speakers will include Dr Douglass V. Brown, Mr George St. J. Perrott and Dr Elliott P. Joslin of Boston, Dr Hugh Cabot of Rochester, Minnesota, and Dr John P. Peters, of the Yale University School of Medicine. Dr Richard H. Overholt will present a colored motion picture entitled "Thoracic Surgery."

Clinics have been scheduled for Monday, April 3 at the Boston City and the Joseph H. Pratt Diagnostic hospitals

### LAWRENCE CANCER CLINIC

The regular Lawrence Cancer Clinic, to be held at the Lawrence General Hospital, 1 Garden Street, Lawrence, on Tuesday, April 4, at 10 00 a. m., will be a demonstration and teaching clinic for physicians, with Dr Channing C. Simmons, of Boston, associate in surgery in the courses for graduates at Harvard Medical School surgeon-in-chief to Collis P. Huntington Memorial Hospital, member of the Cancer Commission of Harvard University, and consulting surgeon to the Massachusetts General Hospital,

present as consultant. Physicians of the north half of Essex County are invited to accompany any of their patients whom they desire to have this service or to send them with a note. A report will be returned to every physician who sends a patient. The service is gratis. Any physician is welcome to attend the clinic.

This clinic is endorsed by the Committee on Postgraduate Instruction of the Massachusetts Medical Society

ROY V. BAKETEL, M.D.,  
CHARLES J. BURGESS, M.D.,  
JOHN J. McARDLE, M.D.,  
HARRY H. NEVERS, M.D.,  
THOMAS V. UNIAC, M.D.,  
J. FORREST BURNHAM, M.D., *Chairman*

### CONSULTATION CLINICS FOR CRIPPLED CHILDREN IN MASSACHUSETTS, UNDER THE PROVISIONS OF THE SOCIAL SECURITY ACT

CLINIC	DATE	ORTHOPEDIC CONSULTANT
Salem	April 3	Harold C. Bean
Haverhill	April 5	Arthur T. Legg
Lowell	April 7	Albert H. Brewster
Gardner	April 11	Mark H. Rogers
Springfield	April 12	Garry deN. Hough, Jr
Brockton	April 13	George W. Van Gorder
Pittsfield	April 17	Francis A. Slowick
Worcester	April 21	John W. O'Meara
Fall River	April 24	Eugene A. McCarthy
Hyannis	April 25	Paul L. Norton

### MASSACHUSETTS PSYCHIATRIC SOCIETY

The next meeting of the Massachusetts Psychiatric Society will be held at the Boston Psychopathic Hospital on Friday, March 24, at 8 00 p m.

#### PROGRAM

Localization of Cortical Lesions by Electroencephalography Dr Hallowell Davis

The Cortical Frequency Spectrum in Epilepsy Dr Fred A. Gibbs.

Some Clinical Uses of the Delta Index with Special Reference to Schizophrenia. Dr Hudson Hoagland.

Electroencephalography in a Mental Hospital Miss Pauline A. Davis

General discussion will follow

W. FRANKLIN WOOD, M.D., *Secretary*

### HOSPITAL RESEARCH COUNCIL

The next meeting of the Hospital Research Council will be held in the Ether Dome of the Massachusetts General Hospital on Tuesday, March 28, at 5 00 p m.

#### PROGRAM

Vitamin C Lack After Major Surgery Dr Chester M. Jones

The Determination of Serum Proteins Dr Bernard M. Jacobson

## BOOKS RECEIVED FOR REVIEW

*Anemia in Practice Pernicious anemia* William P Murphy 344 pp Philadelphia and London W B Saunders Co., 1939 \$5.00

*Pulmonary Tuberculosis A synopsis* Jacob Segal. 150 pp New York, London, Toronto Oxford University Press, 1939 \$2.75

*Bacteria The smallest of living organisms* Ferdinand Cohn (1872) Translated by Charles S Dolley (1881) 44 pp Baltimore The Johns Hopkins Press, 1939 \$1.00

*Life's Beginning on the Earth* R. Beutner 222 pp Baltimore The Williams & Wilkins Co., 1938 \$3.00

*The New International Clinics* Original contributions clinics, and evaluated reviews of current advances in the medical arts Edited by George M. Piersol. Vol. 1, n. s. 2. 312 pp Philadelphia, Montreal and New York J B Lippincott Co, 1939 \$3.00

*Transactions of the American Gynecological Society* Edited by Richard W TeLinde. Volume 63 For the year 1938 296 pp St. Louis The C V Mosby Co, 1939

*A Treatise on the Surgical Technique of Otorhinolaryngology* Georges Portmann. Collaborators H. Retrouvey, J Despons, P Leduc and G Martinaud. Translation by Pierre Viole. 675 pp Baltimore William Wood & Co, 1939 \$12.50

*Problems of Ageing Biological and medical aspects* Edited by E. V Cowdry 758 pp Baltimore Williams & Wilkins Co, 1939 \$10.00

*Biochemistry for Medical Students* William V Thorpe. 475 pp Baltimore William Wood & Co, 1939 \$4.50

*Chemical Analysis for Medical Students Qualitative and volumetric* R. E. Illingworth. 151 pp Baltimore William Wood & Co., 1938 \$1.50

## BOOK REVIEWS

*Marihuana America's New Drug Problem A sociologic question with its basic explanation dependent on biologic and medical principles* Robert P Walton. 223 pp Philadelphia, London, Montreal, Chicago and New York J B Lippincott Co, 1938 \$3.00

Hemp—the plant and its derivatives have passed under different names according to time and place—has long been abused as a narcotic, particularly in the Orient. It is only within the past half decade, however, that its use has become a widespread menace in these United States, a menace the greater in that the drug has been employed chiefly by those hardly beyond childhood. Enough concerning marihuana has appeared in the press and in popular periodicals to excite people's fears, but it has remained for Dr Walton to attempt a critical survey of all our available knowledge, a task that has involved a combing of popular as well as scientific literature.

The result is a work which is both timely and scientific and which furnishes information that should be of material aid in efforts to discover a solution of the problem. Parents of adolescents, educators, social service workers, agents of the law and, of course, physicians, should all find in this book matters of interest and import. For those who would pursue further particular phases of the subject there are excellent bibliographies.

The Evidence for Endocrine Control of Serum Amylase Activity Dr Oliver Cope.

Response of Myxedema to Iodinated Proteins Dr Jacob Lerman

HENRY K BEECHER, M.D., *Secretary*

### AMERICAN HEART ASSOCIATION

The Fourteenth Scientific Sessions of the American Heart Association will be held at the Hotel Jefferson, St. Louis, Missouri, on Friday and Saturday, May 12 and May 13

The general cardiac program will be given on Friday, and the program of the section for the study of the peripheral circulation, on Saturday

### AMERICAN BOARD OF INTERNAL MEDICINE, INC

Written examinations for certification by the American Board of Internal Medicine will be held in various sections of the United States on the third Monday in October and the third Monday in February

Formal application must be received by the secretary before August 20 for the October 16 examination, and on or before January 1 for the February 19, 1940 examination.

Application forms may be obtained from Dr William S Middleton, secretary treasurer, 1301 University Avenue, Madison, Wisconsin

### MEDICAL CLINIC AT THE PETER BENT BRIGHAM HOSPITAL

At 3 30 p m on Thursday, March 30, in the amphitheater of the Peter Bent Brigham Hospital, Dr James P O'Hare will give a medical clinic Practitioners and medical students are cordially invited to attend

### NEW ENGLAND HEALTH EDUCATION INSTITUTE

The New England Health Education Institute, sponsored by the New England Health Education Association, the State Departments of Health, the State Departments of Education and the State Tuberculosis Associations of Maine, New Hampshire, Vermont, Massachusetts, Rhode Island and Connecticut, will be held at the Massachusetts Institute of Technology, William Barton Rogers Building, 77 Massachusetts Avenue, Cambridge, Massachusetts, on April 21 and 22

### UNITED STATES CIVIL SERVICE EXAMINATIONS

Associate Public Health Nursing Consultant, \$3,200 a Year  
Assistant Public Health Nursing Consultant, \$2,600 a Year

Applications must be on file with the United States Civil Service Commission at Washington, District of Columbia, not later than April 10

Candidates must have successfully completed a full four-year course leading to a bachelor's degree in a college or university of recognized standing, including or supplemented by at least eighteen hours in public health nursing They must have graduated subsequently to January 1, 1918, from an accredited school of nursing affiliated with a hospital having a daily average of fifty or more bed patients and they must be registered graduate nurses in a state or territory of the United States or in the District of Columbia

Associate Medical Officer, \$3,200 a Year

Applications must be on file with the United States Civil Service Commission at Washington, District of Columbia, not later than April 10

Candidates must have graduated from a medical school of recognized standing with the degree of M.D., subsequent to May 1, 1934 They must have had at least one year internship, general, or one year in a special branch. Applications will be received from persons who are now serving one-year internships They will not be certified for employment, however, until proof of satisfactory completion of one year internship is furnished to the Commission

### WORCESTER DISTRICT MEDICAL SOCIETY

The next meeting of the Worcester District Medical Society will be held at the Worcester Hahnemann Hospital on Wednesday, April 12

Dr Meredith F Campbell, professor of urology at New York University College of Medicine, will speak on 'Urogenital Diseases of Infants and Children.' Discussion will be opened by Drs E Granville Crabtree and Bancroft C Wheeler

GEORGE C TULLY, M.D., *Secretary*

### BOSTON DISPENSARY

A luncheon meeting of the clinical staff of the Boston Dispensary will be held on Friday, March 31, in the auditorium of the Joseph H. Pratt Diagnostic Hospital at 12 o'clock noon.

#### PROGRAM

The Pathology of Sinusitis Dr Philip E Meltzer  
The Treatment of Sinusitis Dr Lyman G Richards

All interested in the subject are cordially invited to attend

ROBERT W BUCK, M.D., *President*,  
JAMES M. BATY, M.D., *Secretary*

### TUFTS COLLEGE MEDICAL SCHOOL ALUMNI ASSOCIATION

The annual meeting and dinner of the Tufts College Medical School Alumni Association will be held Wednesday evening, March 29, at the Hotel Somerset, Boston.

Changes in the medical school and progress of the medical school campaign will be discussed by President Leonard Carmichael

ALONZO K. PAINE, M.D., *President*

## CANCER OF THE OVARY\*

JOE V MEIGS, M.D.†

BOSTON

IN the *Southern Medical Journal* for February, 1937, there is an article<sup>1</sup> on cancer of the ovary, with a review of all the cases treated at the Massachusetts General Hospital from 1901 through 1931, a period of thirty-one years. Because the results of treatment of these malignant epithelial tumors of the ovary were so poor the series was brought up to 1934, a period of thirty-three years. The outlook for patients with this disease is so hopeless that it seemed pertinent to present the subject here in the hope that a greater interest could be stimulated in early diagnosis and in earlier and more radical treatment. Cancer of the cervix shows absolute curability of 24 per cent in the series at the Massachusetts General Hospital, and cancer of the breast with axillary involvement, a 25 per cent arrest for five years. In the recent Pondville series<sup>2</sup> the five-year survivals for cervical cancers have been raised to 34.5 per cent through a combined use of x-ray and radium. The five-year end results for malignant epithelial lesions of the ovary are worse than the above series, and show only 24 patients out of 147, or 16 per cent, living without demonstrable disease. Thus the seriousness of this group of tumors is easily appreciated. Yet if earlier symptoms could be interpreted and earlier diagnoses be made, the end results should be much better, for the tumors in their early stages are easily dealt with.

### MATERIAL

During the years 1901-1933 inclusive there were 147 patients with cancer of the ovary. The history of each case was carefully abstracted, the slides of each tumor were reviewed and studied, and any doubtful tumors were taken for review by the hospital pathologist, Dr. Tracy B. Mallory. If a tumor was classified as malignant on the hospital record but if this diagnosis was not confirmed on the review of the slides, it was discarded.

Presented at the annual meeting of the New England Surgical Society, Boston, October 1, 1938.

†Instructor in surgery, Harvard Medical School; visiting surgeon, Massachusetts General Hospital.

Furthermore, some patients with cystadenomas of the ovary which were believed to be benign were included in the malignant group after restudy of microscopic sections. No case was accepted for this series if the diagnosis was made on a biopsy specimen from the peritoneum unless the surgeon was certain that the lesion originated in the ovary, and no metastatic tumor of known or unknown origin was accepted. Thus all cancers of the ovary with the primary lesion in the endometrium were discarded, as well as tumors metastasizing from the stomach (Krukenberg) or intestine. There were a few patients with generalized peritoneal implantations which were called malignant in the old records, if these lesions looked benign microscopically and the patient was still living after five years, the diagnosis was regarded as incorrect and a proper one of benign papillary cystadenoma of the ovary with peritoneal implantation was substituted. All tumors of peculiar or "odd" types were excluded, such as granulosa-cell carcinomas, dysgerminomas, Brenner tumors, sarcomas, teratomas (dermoids), and so forth. If no slides were available for study, the case was excluded at once. In all, more than 250 tumors of malignant types were reviewed and all but 147 were discarded. The remaining group is a selected one, but includes as few benign and "odd" cases as is possible. The history and end result, with microscopic study of the tumor by the hospital pathologist and surgeon, should be made the ideal for reports of the end results of cancer treatment. The possibility of misinterpretation in the pathological laboratory when clinical information is not available is very great. Much more valuable information would be available from the literature if no reports were presented without a complete recheck of each case at the time the reports are made.

### EMBRYOLOGY OF THE OVARY

Because of the multiplicity of tumors that originate in the ovary, an abbreviated description of its embryology is presented.

*Clinical Laboratory Methods and Diagnosis A textbook on laboratory procedures with their interpretation*  
R B H. Gradwohl Second edition 1607 pp  
St. Louis The C V Mosby Co., 1938 \$12.50

To the above description of this book one might add that it has 492 illustrations in the text, 44 colored plates and weighs 8 pounds and 4 ounces. In the preface to the edition the author states. Of particular moment in the improvement of this book are the following: a description of the newer concepts on nephritis and nephrosis, according to the viewpoints of Fishberg, Smith, Berglund and others; amplification and simplification of the chapter on blood chemistry, with an adoption of standard modern methods and the elimination of methods no longer generally practiced. More than one hundred pages have been added to the chapter on hematology. Complete data on the theories of blood development are given. New technical measures have been set forth. The value and technical methods of blood sedimentation tests are fully described. The Schilling theory has been further elaborated. Aside from textual improvement, twenty-four full page color plates have been added—a veritable atlas of hematology.

As an uncritical assembly of unrelated topics, this book has no equal. Why any book on clinical laboratory methods should contain approximately 200 pages suitable to a textbook of bacteriology, 90 pages on postmortem examinations, tissue cutting and staining and the preparation of museum specimens, 50 pages on toxicological technique, 42 pages on the detection of crime by laboratory methods, and almost 200 pages on parasitology and tropical medicine, the reviewer is unable to state. Each of these subjects would appear to deserve a separate textbook. The section devoted to postmortem pathology and toxicological technique is inadequate. The detection of crime by laboratory methods has no connection with clinical laboratory methods. Parasitology, as treated in this volume, is more properly a division of protozoology. This last section contains extremely good photographic reproductions, but many are repetitious. In fact, the only portion of the book which is not illustrated is the index. There are a dozen or more illustrations of microscopes, innumerable pictures of common laboratory apparatus, such as a shaking machine for the manufacture of vaccines, an electric warm stage, a bottle for the collection of feces, bunsen burners, electric incubators, coverglass holders, and so forth. Why any author of a textbook of laboratory methods has to assume that the users of his book have never before seen the inside of a laboratory is beyond comprehension.

If all the repetitions, useless illustrations and non-pertinent subject matter could be eliminated and this book reduced to about one fourth its present size, it might prove to be a convenient reference for the clinician and laboratory worker.

*Tuberculosis Among Young Women* Edna E. Nicholson 67 pp New York National Tuberculosis Association, 1938

This important problem has finally been taken out from the realms of conjecture, guesswork and moralization and put on a sound scientific basis. The subject of the high rate of tuberculosis mortality among adolescent young women has been a favorite topic of the self-styled medical expounders and moral preachers, who found many figures in support of their pet theories as to why such a condition exists.

This study was approached in a very thorough and

scientific manner by Miss Edna E. Nicholson, and the material was first published by the National Tuberculosis Association as their Social Research Series (Nos. 1 and 4). After studying the various factors that have been enumerated as a possible cause of the increased mortality, Miss Nicholson concludes, although her ideas do not lend themselves to absolute proof, that the increased mortality rate is due to the psychic and physiologic changes that take place among young women in the adolescent age. In other words, the cause is biologic and not necessarily environmental—although environment does play a part. The deduction appears to be quite sound, as the mortality in this group has always been high.

This survey should be of very great interest to all physicians who deal with the problem of tuberculosis and all persons who have the responsibility of maintaining and caring for the health of young adolescent women.

*La Ponction Sternale Procédé de diagnostic cytologique*  
P. Émile Weil and Suzanne Perles 183 pp Paris  
Masson et Cie, 1938 75 Fr. fr

This short monograph on sternal puncture contains up-to-date information in regard to this procedure. There is a section describing the normal myelogram, and one portraying the pathologic myelogram. In the latter there are chapters on the leukemias, leukemoid reactions, tumors of the marrow (chloromas, myelomas, reticuloendothelomas), metastatic tumors, the anemias, polycythemia, erythroblastosis, eosinophilia, infectious diseases, hepatomegalies, splenomegalies and adenopathies. The work contains numerous illustrations, the majority black and white drawings, and a number of colored reproductions. The latter are particularly well done. There is a long bibliography referring to papers in the French, German, Italian and American literature. There is some suspicion, however, that not all the references were actually read since there are occasional ludicrous errors in the names of the journals. On the whole, however, the work will be of value to those interested in hematology.

*The Principles and Practice of Obstetrics* Joseph B. De Lee  
Seventh edition 1211 pp Philadelphia and London  
W. B. Saunders Co., 1938 \$12.00

This seventh edition of Dr. De Lee's textbook of obstetrics is as thoroughly excellent as its predecessors. It has been completely revised and now contains 1277 illustrations, 271 of them in color. The chapters dealing with the practical application of obstetrics rightly emphasize conservatism; they have been little changed. Because nearly two thirds of the births in the United States occur in private homes, the technique of home delivery, covering all complications, is emphasized. The chapters on the physiology of menstruation and nidation of the ovum and the blood chemistry of toxemia of pregnancy have been practically rewritten, that on obstetric analgesia and anesthesia has been brought up to date, as well as those dealing with the medical complications of obstetrics. Much space has been devoted to the mechanism of labor, and the length of the chapters on contracted pelvis illustrates the importance of this condition in Dr. De Lee's mind. He bemoans the frequent use of cesarean section for this condition and states that a better understanding of the pelvis and of the mechanism of labor in contracted pelvis would oftentimes make the operation unnecessary. The chronological appendix is still a valuable contribution. The volume now extends to 1170 pages, with a complete cross-reference index of 30 pages.

and cystic, white, yellow, hemorrhagic, and so forth. There is no way of predicting what the histological picture will be from the gross appearance of the tumor, except that the so-called pseudomucinous tumor has typical pseudomucinous epithelium, whether or not it is malignant is impossible to say. Histologically three types of epithelium were recognized—the pseudomucinous, the endometrial and a large unclassified group. The easiest type to differentiate histologically is the pseudomucinous, with its high columnar cells containing large amounts of pseudomucin. The solid pseudomucinous tumor is usually made up of masses of abnormal but yet recognizable pseudomucinous epithelium. This solid type of tumor is a rarity. Another type that grows in papillary and solid forms resembles the epithelium of the endometrium. Inasmuch as the celomic epithelium produces the covering of the ovary and the Müllerian ducts, and since these ducts give rise to the endometrium, it is not surprising to find an endometrium-like tumor. Some areas in such a tumor may not suggest endometrium, and this finding probably indicates the extremely atypical character of its growth. Tumors of the so-called unclassified type are histologically different and complex, though after long study certain types are becoming more and more familiar. Their epithelium varies from well-differentiated to very undifferentiated cell types. The most bizarre and peculiar types of cells and structure may be present. This group is one of exclusion, for if the tumor could not be classified as pseudomucinous or endometrial it was placed in the unclassified group.

The criteria of malignancy used were the evidence of atypicality of cells, the presence of mitotic figures, the invasion of the walls of cysts with growing cells, undifferentiation and, in the papillary growths, the presence of areas which if seen alone would be classified as adenocarcinoma. There was no doubt of the malignancy of the tumors included in the group under study. The end results as presented seem to justify the grouping. No doubt a few mistakes have been made, but the malignancy or benignity of a tumor was usually decided from the history and the microscopic slide, and the end result was then checked. If there was a doubt as to malignancy and if the patient was living and well without disease, this tumor was classed as benign.

Grossly the tumors were divided into the following three groups—solid, and solid and cystic, malignant papillary cystadenoma with areas of adenocarcinoma, and malignant papillary cystadenoma. These divisions are primarily clinical and the separation of the two types of malignant

papillary cystadenomas usually necessitates histological differentiation. Combining the latter two, however, makes two fairly easily separated groups. The difference in prognosis between the solid group and the cystadenoma group suggests that two groups are sufficient. The division of the cystic groups is presented because of their histological difference.

#### SOLID, AND SOLID AND CYSTIC, CARCINOMA OF THE OVARY

This group is by far the most serious. Its operability is small and the prognosis very poor. By the solid type is meant a tumor with no cysts except those caused by areas of necrosis. The solid and cystic tumors are those with thick walls invaded by cancer and with large masses of cancer tissue present inside or outside the cyst. There may be marked necrosis and liquefaction or a huge growth of carcinoma from and into the wall of a malignant cyst. The tumor may be large or small, but must have at least half the bulk made up of solid cancer tissue. These tumors grow as medullary carcinoma, adenocarcinoma or papillary adenocarcinoma. The type of cell may be any one of the three types described above. Certain cases in this group may be the result of a malignant papillary cystadenoma which has grown beyond the cyst stage into the solid stage. The preoperative diagnosis is difficult. The symptoms and physical findings are presented in Table 1. A study of the cases makes one feel that any

TABLE 1 *Summary of Clinical Data on 67 Cases with Solid Carcinomas of the Ovary*

CLINICAL DATA	PERCENTAGE OF CASES POSITIVE

woman past the age of forty who has in either vault a hard area suggestive of an ovarian lesion must be urged to be operated on at once. There is no method of making an accurate diagnosis except by operation or perhaps by peritoneoscopy. These tumors may be accompanied by abnormal bleeding before or after the menopause. In this series 37 per cent were bilateral, and it is probable that more were or had been bilateral. It is certain that in patients with solid cancer of the ovary it is

The ovary arises as a mass of mesenchyme on the back wall of the abdominal cavity. Germinal epithelium from the pelvic or celomic epithelium surrounds this mass. The ova arise either from the hind gut or the germinal epithelium and migrate into the mass. The connective tissue surrounding the ova becomes highly specialized and forms the granulosa and thecal cells of the follicles. Thus in the depth of the gonad and from mesenchyme arise structures that can eventually become epithelial—for instance the lining of certain follicle cysts. It is possible that the primitive ova are not the ones that develop into mature ova with their surrounding follicular apparatus. It may be that new eggs arise in the germinal epithelium during adult life, find their way into the cortex of the ovary and develop there.

The gonad is probably neither ovarian nor testicular at the beginning, but its development depends on the presence of sperm or ova. If abnormal ova are present, cells that ordinarily become granulosa or thecal may become testicular or tubular (Sertoli). The gonad has also been considered as testicular at first and later cupped by ovarian tissue, the testicular tissue then atrophies and the organ becomes an ovary. Either possibility explains the presence of testicular tissue in the ovary. Thus it becomes a source of tumors of the male type.

The adrenals and the kidneys develop in close proximity to the gonad, and the possibility of the inclusion of a few cells of these organs is great. Certain peculiar tumors of the ovary suggest a source such as this. The special tumors that we recognize now point to such possible sources—granulosa cell, thecal cell, testicular, tubular, Leydig cell, and so forth. All tumors of special types are excluded from this group for the more highly specialized the tumor the less is its malignancy. In the group accepted there must be many tumors that will be defined as special tumors as our knowledge increases. Therefore it may be that many of our surviving patients were blessed with highly specialized but at present unrecognized tumors. The exclusion of such lesions would greatly alter the results.

#### SYMPTOMS AND DIAGNOSIS

Ovarian cancer often gives no symptoms until it is well advanced. Frequently increase in size of the abdomen due to tumor is considered as increasing weight and heaviness due to the age of the patient. There may be early a sense of vaginal discomfort and occasionally a slight gastrointestinal upset, but later the chief symptoms are pelvic pain and discomfort, loss of weight and urinary difficulty. Ascites is not uncommon, but it must

be remembered that a solid pelvic tumor with ascites and even hydrothorax does not indicate a hopeless prognosis, because fibromas of the ovary, benign cysts and even fibroids may be accompanied by ascites and fluid in the chest.

*Age* About half of all patients with ovarian tumors are in the age group of thirty to fifty, more in the older decade than in the younger. Ten per cent are from ten to thirty, while slightly over 40 per cent are from fifty to seventy. In the most malignant group 51 per cent fall into the thirty to fifty group, while 45 per cent were found to be between fifty and seventy. Ovarian cancer is a tumor of older women.

*Marital History* In this series 119 patients, or 81 per cent, were married, of the married women but 63 per cent had had children. This is a low incidence of fertility, as the usual figure is approximately 90 per cent. In nearly all statistical studies this finding is persistent. Lynch's<sup>3</sup> paper, written in 1936, showed that but 69 per cent of his patients had had children. These figures in a nearly comparable series of cases tend to show that non-fertility is an important factor. Therefore it is necessary to consider the possibility of some sort of congenital defect of the ovary in this group of patients, for if a congenital developmental defect were present there should be an increased chance for the growth of left-over cells and, hence, for the production of abnormal growths.

*Menstrual History* In this series of 147 patients, 48, or 33 per cent, of those still menstruating had regular menstrual periods. Eight, or 5 per cent, were irregular, 18 or 12 per cent, did not give this information in their hospital histories. Seventy-three, or 50 per cent, had had the menopause. Of those past the menopause 15, or 10 per cent, had bleeding as a symptom. Probably the ovary was still secreting enough hormone to affect the endometrium so that the bleeding occurred for physiological reasons. It is doubtful that "congestion" was responsible. It is conceivable that some of the peritoneal implants which disappear after the main tumor is removed do so because ovarian hormone stimulation has been stopped. Many reports have been made of the hormone content of ovarian cyst fluids, and certainly in many the amount of estrin present might account for endometrial changes. Abnormal bleeding after the menopause in the presence of a pelvic mass should immediately make one consider the possibility of ovarian cancer.

#### TYPES OF TUMORS GROSS AND HISTOLOGIC

The group of tumors were of all sorts—large, small, papillary, smooth-walled, cystic, solid, solid

exception in the proper management of malignant lesions of the ovary

Before making a tremendous incision in the abdominal wall in the presence of a huge ovarian tumor it is often a great question as to whether or not it is safe to tap the cyst. The figures of this study (Table 4) and the previous one<sup>1</sup> show that statistically no harm comes from rupture or from tapping a cyst. This is probably due to the small number of cases, for the spilling of the contents of a

into the two types, the patients with more malignant tumors that were bilateral fared worse than those with less malignant ones. It appears from this study that the patients with bilateral lesions had a more serious prognosis than did those with single tumors.

In our hospital figures the surgeons removed only one ovary in 30 per cent of the patients with operable solid tumors, 41 per cent of those with malignant papillary cystadenomas with adenocar-

TABLE 4 *Miscellaneous Data*

TYPE OF CANCER	ALL CASES		PER CENT RECURRENT IN OTHER OVARY	UTERINE INVOLVEMENT		ADHESIONS		CYST RUPTURED BEFORE OR DURING OPERATION	
	NO	PER CENT LIVING		PER CENT ALL CASES	PER CENT LIVING	PER CENT ALL CASES	PER CENT LIVING	PER CENT ALL CASES	PER CENT LIVING

Without adenocarcinoma	43	23	2	7	0	47	30	30	31

papillary cyst usually spreads particles of tumor that are in the cyst fluid and this is liable to be harmful. In operating on other cancers, cutting across or spilling tumor is considered dangerous, and there is corresponding danger here. However, Hodenpyl<sup>1</sup> years ago advocated the treatment of cancer with ascitic fluid from patients suffering with malignant disease because he felt it was in some way inimical to cancer growth. It is possible that the fluid of these cysts may be an inhibitor of cancer growth. Nevertheless, it seems safer to avoid spilling and rupture if possible.

**Inoperable Growths** There were many inoperable cases in this series (Table 3), the patients were simply explored, a biopsy was taken and the incision was closed. In over a quarter of the solid-tumor group and in one seventh of the cystic group this was all that could be done. There were more patients in the former group who had a short history from onset to operation and more died in the

cinoma in the wall and 32 per cent of those with malignant papillary cystadenomas. Thus, in spite of the fact that a high percentage are bilateral

TABLE 5 *Operative Mortality and One-Year Mortality in All Cases*

Without adenocarcinoma	43	5	56

we failed to take advantage of our knowledge of ovarian tumors. It is a matter of interest, however, to find that only 5 per cent of the patients in the more malignant cystic group came back for removal of another tumor of the ovary, and only 2 per cent of those in the less malignant group, while none returned in the solid group (Table 4). All cases have been followed carefully for some

first year after operation, showing that this type of cancer is definitely a more serious one than the cystic type.

**Bilateral Tumors** In this series the survival rate of patients with bilateral solid tumors is below that of the entire group, but it is better in the cystic group (Table 3). Dividing the latter group

time, so this fact is certainly interesting. It is probable that we have been more lucky than wise.

#### OPERATIVE MORTALITY AND FIVE-YEAR SURVIVALS

In the solid group the operative mortality was only 10 per cent, and many of these patients were in poor condition (Table 5). In the two cystic

necessary that both ovaries, the uterus and cervix be removed if possible. No attempt should be made to conserve ovarian tissue. These tumors metastasize far and wide, and patients may return after the five-year period from operation has been passed with metastatic nodules in various parts of their bodies. X-ray treatment is of some value in prolonging the lives of patients in this group, but a cure cannot be expected.

#### MALIGNANT PAPILLARY CYSTADENOMA WITH AREAS OF ADENOCARCINOMA

The division of malignant papillary cysts into two groups has justification, for the end results show that the type with areas of adenocarcinoma is more serious than a simple malignant papillary cystadenoma. Any papillary cystic tumor that microscopically has an area that suggests

adenocarcinoma in its walls is included in this group. The pseudomucinous cysts are the least malignant and the endometrial type the most. The lesion spreads, as do the solid types, but not quite so widely and rapidly. The same type of radical surgery should be used for this tumor.

#### MALIGNANT PAPILLARY CYSTADENOMA

This tumor is not so malignant as the other two, yet its treatment is not satisfactory. Here again

TABLE 3 Type of Operation in All Cases

TYPE OF CANCER	NO OF CASES	PER CENT INOPERABLE	UNILATERAL OOPHORECTOMY		BILATERAL OOPHORECTOMY		BILATERAL TUMORS	
			PER CENT ALL CASES	PER CENT LIVING	PER CENT ALL CASES	PER CENT LIVING	PER CENT ALL CASES	PER CENT LIVING
Solid carcinoma	67	25	22	7	43	18	37	8

With adenocarcinoma	37	8	38	29	51	21	43	17
Without adenocarcinoma	43	21	26	27	35	33	40	41

the pseudomucinous type is the least malignant and the endometrial the most. Metastasis is not so common as it is in the other two groups, but it does occur. Great care should be taken to prevent spilling of the contents of these cysts

#### TREATMENT

The required treatment of all groups is operative, as an accurate diagnosis cannot be made without surgery, and operation should be advised early and insisted upon. The peritoneoscope should prove of inestimable value in making the diagnosis. It should be used by one accustomed to the instrument, and great care should be exercised not to perforate the growth. Just as the colposcope, the cystoscope and the proctoscope are of enormous value, so eventually may the peritoneoscope become.

Treatment should consist of radical surgery. Whenever possible both the ovaries, the uterus and the cervix should be removed. A good rule in cases of ovarian cancer is to remove as much tumor tissue as is possible, and also all the genital organs if the patient's condition permits. Because these various tumors are so apt to be bilateral, and because ovarian tumors may metastasize to the other ovary, both ovaries should be removed (Table 3). If possible a total hysterectomy should be done, for ovarian tumors can metastasize to the cervix by way of a chain of lymphatics in the uterine musculature. Certain schools advise leaving the uterus behind so that it can be used as a locus for radium therapy. Inasmuch as surgery is the best means of treatment and because the new x-ray apparatus can deliver lethal dosage into the pelvis, it is safer to remove the uterus than to leave it for subsequent radium treatment.

It is extremely important to open an ovarian tumor before finishing the operation, for papillary projections may be found within the cyst, and in these tumors papillary projections suggest malignancy. If such processes are found on the outside of the cyst it is best to adopt radical surgery and remove all the pelvic organs. If papillary projections are found in a freely movable tumor and if the patient is young and wants children, conservation is justifiable. In such cases it is important that the patient be seen at least every six

months for five years or more, because if a neoplasm can develop in one ovary the same embryonic background is probably present in the other and a tumor may develop in it. Radical surgery is the rule and conservation of ovarian tissue the

treatment lie outside the scope of this paper. The gross results obtained by radiation in about 40 per cent of all the cases of cancer of the ovary reported are shown in Table 7. An important figure is that of the radiation group of solid cancers, with 7 per cent living five years without disease. This must be contrasted with a salvage of 14 per cent in a similar group not radiated. In the malignant papillary cystadenoma group the radiated cases did better than the non-radiated ones, but in the group with adenocarcinoma in the walls of the cyst, the non-radiated cases did better than the radiated. However, there is not much to choose between a 21 per cent salvage of radiated cases in the combined group and a 23 per cent salvage of non-radiated cases. The groups were fairly comparable, there being inoperable cases in both groups, and cases in which death from cancer occurred six to fifteen years later.

It is apparent from this study, so far as it goes, that no more people are cured with radiation than without it. Up to the present time the greatest reliance should be placed on surgery. It is more hopeful, however, to view the length of life in months of these patients having radiation as compared with those not having it, and here it is clear that in the most malignant type, the solid tumors, radiation prolonged life, but in the cystic groups life was longer without it. The whole series shows that the treatment given was not of too great value. It is my belief, however, that much better results will be forthcoming, and that further analysis of this particular group, with due consideration given to the extent of disease and the amount and type of radiation, may show that radiation of ovarian cancer is of greater value than now appears. But, without picking cases, this type of therapy has not proved so valuable as we thought it would.

#### DISCUSSION

Cancer of the ovary is a very serious lesion, and the solid type rates with the very worst of all malignant tumors. The record of our hospital is not satisfactory, but it probably represents the results in the community at large. Comparable series must eliminate all questionable tumors, must rule out all special tumors and must make sure that no non-malignant papillary cystadenomas are included. This series has been carefully studied and each case accepted only after careful consideration, it presents a gloomy picture, but I believe it is a correct one.

It found early, cancer of the ovary is curable, for it is often encapsulated in the ovary and is not serious until the cyst is broken or perforated or

the tumor has grown through. Therefore early operation is essential in patients with questionable ovarian lesions. It is far better to remove a simple cyst or a fibroid because of a mistaken diagnosis than to wait to see whether a given lesion becomes malignant. The use of the peritoneoscope must be encouraged, and when it plays a more prominent part in the diagnosis of pelvic disease I believe that our figures will improve. The preservation of ovarian tissue in women with ovarian cancer or papillary cysts—benign or malignant—is serious, and if this is done in order to allow pregnancy to occur, extreme caution must be exercised in the follow-up, care being taken that a lesion does not start in the other ovary.

Tapping of cysts is probably not a sound procedure, but the figures in this paper do not prove it, in fact they suggest the contrary. It is safer to advise against tapping, but if a cyst is ruptured the surgeon should not give up hope, as he has the figures of this series of cases and Hodenpvl's<sup>4</sup> advice as precedents.

#### SUMMARY AND CONCLUSIONS

Cancer of the ovary of the solid type is a very serious neoplasm.

Cancer of the ovary of the malignant papillary cystadenoma type is about as malignant as any other epithelial growth.

Early diagnosis and methods with that in view are necessary to improve the end results of this easily operable tumor.

The use of the peritoneoscope should prove of great value in diagnosis.

Bilateral tumors are more serious than unilateral ones.

Bilateral oöphorectomy with total hysterectomy is the operation to be carried out if possible.

Postoperative mortality is low.

The rupture of cysts before and during operation and the use of the trocar cannot be proved dangerous by our end results, nevertheless, avoidance of spilling of cyst contents is advocated.

X-ray treatment to date has not proved of much curative value, but more modern methods of treatment may give greater success.

Every cystic or solid tumor of the ovary that is removed should be opened before the surgeon ends his operation, in order to rule out the presence of any suspicious papillary area.

groups the mortality was 3 and 5 per cent, a fairly satisfactory result

The results of surgical treatment, including the cases that had x-ray therapy, show that in the solid and the solid and cystic group only 9 per cent of 67 patients survived five years (Table 6). In the more malignant group of papillary cysts,—that is, those with adenocarcinoma in the wall of the tumor,—22 per cent are living, while in the malignant papillary cystadenoma group 23 per cent have survived five years. The end results according to histological classification show that the most favorable types in the solid group are those of the endometrial type, with 18 per cent living, the pseudomucinous type was the worst. Taking the two cystic types together, there are 23 per cent of 80 cases living five years. Inasmuch as many of these cysts looked fairly benign, the end

it should in any way replace surgery. Whatever can be removed surgically should be, and it should not be assumed that if all the tumor cannot be taken out roentgen-ray treatment will care for the rest. It will prolong life but will not cure cancer. The changes in tumors observed following x-ray treatment in large numbers of cancers of the cervix are most convincing. Roentgen radiation will slow up the growth of cancer deep in the pelvis, both in the gross and microscopically, but it will not cure it. The present method of treating metastatic ovarian cancer can be improved upon, for although it is necessary to treat the entire abdomen, the usual procedure is to treat only two or three fields. This treatment cannot adequately cover the entire abdominal cavity, so that unless each field is marked off and treated, certain areas are sure to be missed. It is very im-

TABLE 7 *Results of Roentgen Radiation*

TYPE OF CANCER	NO OF CASES	RADIATED		NON RADIATED		PERIOD BETWEEN OPERATION AND DEATH	
		PER CENT ALL CASES	PER CENT 5 YR SURV	PER CENT ALL CASES	PER CENT 5 YR SURV	RADIATED	NON RADIATED
Solid carcinoma	67	45	7	55	14	78	167
Malignant papillary cystadenoma	80	41	21	59	23	32	41
With adenocarcinoma	37	46	18	54	25	27	34.5
Without adenocarcinoma	43	37	25	63	22	37.5	47.5

results are appalling. The unclassified and the pseudomucinous types did best, with 26 per cent in each group surviving five years, and the endometrial type did poorly, with only 12 per cent survivals.

It is well to consider the endometrial type. This tumor, like cancer of the endometrium, does not become very malignant until it has grown outside the ovary or uterus. Once free in the peritoneal cavity it is one of the most malignant of all pelvic tumors. In a series<sup>5</sup> of cases of cancer of the endometrium reported from the Pondville Hospital it was found that this tumor metastasized farther and more frequently than did cancer of the cervix and that once it was outside the body of the uterus nothing could check its growth.

The percentage of five-year survivals of malignant papillary cystadenoma of all types is 23, this is a reasonable figure for most malignant tumors. However, the survival rate for the solid types suggests that it is one of the most serious cancers of the human body.

#### ROENTGEN-RAY TREATMENT

There can be no doubt of the therapeutic value of deep radiation, whether given with a 200,000-volt or a 1,000,000-volt machine, but so far it has not been shown in any large group of cases that

portant to insist on adequate and thorough radiation if it is to be given. Perhaps better results will come following the use of high-voltage machines, but this cannot be decided as yet. X-ray treatment should be given in all cases where tumor tissue has been left behind or where there is such a possibility, and it should be given as a prophylactic treatment to those patients in whom a malignant cyst has been ruptured and its contents spilled in the abdomen. If a clean and perfect removal has been accomplished it is safe to omit radiation, but it can be given in these cases also.

The end results of cases of cancer of the ovary following radiation after surgical removal are not well known, although our group is not a large one, it was well followed and studied, and the treatment was the best that could be given at that time in the Massachusetts General Hospital. Most of the cases were treated with a 200,000-volt machine with the usual screening, amperage, and so on. The treatment varied from time to time as it has in other clinics. It is fair to assume that these patients were adequately treated so far as treatment was possible. Undoubtedly better results have been obtained from those treated in the past five years, but it is of no use to report on them at this time. The complete details of radiation

treatment lie outside the scope of this paper. The gross results obtained by radiation in about 40 per cent of all the cases of cancer of the ovary reported are shown in Table 7. An important figure is that of the radiation group of solid cancers, with 7 per cent living five years without disease. This must be contrasted with a salvage of 14 per cent in a similar group not radiated. In the malignant papillary cystadenoma group the radiated cases did better than the non-radiated ones, but in the group with adenocarcinoma in the walls of the cyst, the non-radiated cases did better than the radiated. However, there is not much to choose between a 21 per cent salvage of radiated cases in the combined group and a 23 per cent salvage of non-radiated cases. The groups were fairly comparable, there being inoperable cases in both groups, and cases in which death from cancer occurred six to fifteen years later.

It is apparent from this study, so far as it goes, that no more people are cured with radiation than without it. Up to the present time the greatest reliance should be placed on surgery. It is more hopeful, however, to view the length of life in months of these patients having radiation as compared with those not having it, and here it is clear that in the most malignant type, the solid tumors, radiation prolonged life, but in the cystic groups life was longer without it. The whole series shows that the treatment given was not of too great value. It is my belief, however, that much better results will be forthcoming, and that further analysis of this particular group, with due consideration given to the extent of disease and the amount and type of radiation, may show that radiation of ovarian cancer is of greater value than now appears. But, without picking cases, this type of therapy has not proved so valuable as we thought it would.

#### DISCUSSION

Cancer of the ovary is a very serious lesion, and the solid type rates with the very worst of all malignant tumors. The record of our hospital is not satisfactory, but it probably represents the results in the community at large. Comparable series must eliminate all questionable tumors, must rule out all special tumors and must make sure that no non-malignant papillary cystadenomas are included. This series has been carefully studied and each case accepted only after careful consideration, it presents a gloomy picture, but I believe it is a correct one.

It found early, cancer of the ovary is curable, for it is often encapsulated in the ovary and is not serious until the cyst is broken or perforated or

the tumor has grown through. Therefore early operation is essential in patients with questionable ovarian lesions. It is far better to remove a simple cyst or a fibroid because of a mistaken diagnosis than to wait to see whether a given lesion becomes malignant. The use of the peritoneoscope must be encouraged, and when it plays a more prominent part in the diagnosis of pelvic disease I believe that our figures will improve. The preservation of ovarian tissue in women with ovarian cancer or papillary cysts—benign or malignant—is serious, and if this is done in order to allow pregnancy to occur, extreme caution must be exercised in the follow-up, care being taken that a lesion does not start in the other ovary.

Tapping of cysts is probably not a sound procedure, but the figures in this paper do not prove it, in fact they suggest the contrary. It is safer to advise against tapping, but if a cyst is ruptured the surgeon should not give up hope, as he has the figures of this series of cases and Hodenpyl's<sup>4</sup> advice as precedents.

#### SUMMARY AND CONCLUSIONS

Cancer of the ovary of the solid type is a very serious neoplasm.

Cancer of the ovary of the malignant papillary cystadenoma type is about as malignant as any other epithelial growth.

Early diagnosis and methods with that in view are necessary to improve the end results of this easily operable tumor.

The use of the peritoneoscope should prove of great value in diagnosis.

Bilateral tumors are more serious than unilateral ones.

Bilateral oöphorectomy with total hysterectomy is the operation to be carried out if possible.

Postoperative mortality is low.

The rupture of cysts before and during operation and the use of the trocar cannot be proved dangerous by our end results, nevertheless, avoidance of spilling of cyst contents is advocated.

X-ray treatment to date has not proved of much curative value, but more modern methods of treatment may give greater success.

Every cystic or solid tumor of the ovary that is removed should be opened before the surgeon ends his operation, in order to rule out the presence of any suspicious papillary area.

## DISCUSSION

DR OLIVER N. EASTMAN, Burlington, Vermont I congratulate Dr Meigs on the thoroughness of his study and his able presentation of this important subject, which I believe has received too little consideration in recent literature.

Dr Meigs has brought out the fact that the mortality is very high in ovarian malignancy. This can be accounted for largely by the fact that the symptoms of ovarian malignancy are usually not in evidence until the disease is well advanced. It may be stressed that ovarian tumors are not infrequent, and that the results of treatment will be better when the condition is recognized early and radical treatment instituted.

A pelvic tumor the size of a fist, especially if nodular and associated with irregular bleeding or ascites, warrants surgical investigation. On opening the abdomen, if a warty or papillary growth is noted on the surface of the tumor, radical surgery is indicated.

The ovarian tumors removed in our hospital during the last five years numbered 300. Twelve per cent were essentially or potentially malignant. There were 8 cases of papillary cyst adenocarcinoma, 4 cases of pseudomucinous cyst with malignant involvement and 1 case of malignant teratoma in a child of six. The other cases were questionably malignant. I believe that radical surgical intervention is the treatment of choice in all growths with papillary manifestations, regardless of the histologic characteristics. It is our custom to radiate following the removal of tumors which are suggestive of malignancy.

Will Dr Meigs tell us how he takes care of omentum "cakes" so frequently associated with malignant tumors of the ovary?

DR BENJAMIN H. ALTON, Worcester Dr Meigs's paper is to be commended for several reasons. First, it presents a large series of primary malignant epithelial tumors of the ovary from which have been sorted out those tumors which either clinically or histologically were considered benign or doubtfully malignant. The second point is the method he used in classifying the tumors both grossly and microscopically. A third has to do with the management of these tumors relative to lowering the mortality rate and a frank discussion of certain methods in the treatment of the primary malignant epithelial tumors of the ovary.

This series includes 147 cases, the choice from more than 250 tumors of malignant types, which represents more truly the primary malignant tumors that may arise from the epithelium of the ovaries. To include such tumors as embryomas, granulosa-cell tumors and a number of the cystadenocarcinomas which may be questionably malignant, and which were included in the series of cases reported by Lynch and Murphy, would lessen the value of a study of the real malignant tumors which are responsible for the large number of deaths.

We have observed that the mortality rate in external cancer, such as carcinoma of the breast, lip or skin, has been materially lowered through early recognition and radical removal by surgical means, or obliteration by ray therapy.

With reference to the early recognition of internal cancer, such as cancer of the ovary, Dr Meigs has emphasized certain symptoms and physical findings which are of value. He has also emphasized that the age in which to suspect a malignant tumor of the ovary is between thirty and fifty, the peak being between forty and fifty. The relation of fertility to malignant disease of the ovary is extremely interesting, and in spite of the fact that 64 per cent of the patients in this group of solid carcinoma

were fertile, we cannot infer too readily that sterility is a factor in the production of cancer of the ovary.

In the second group of patients, those having malignant cysts, he shows that the symptoms and physical findings are nearly parallel with those in the solid carcinoma. I believe that we can suspect malignancy of the ovaries sufficiently in cases presenting the above symptoms and physical findings to justify a laparotomy. I agree in principle with Dr Meigs that it is better to remove a benign tumor of the ovary in doing an exploratory laparotomy than to wait until the more classic symptoms of malignancy have developed. As in carcinoma of the breast, we have learned that by the time these symptoms have developed surgical care is practically impossible. I am firmly convinced that any patient between the ages of thirty and sixty presenting the symptoms mentioned demands an exploratory laparotomy, not only as a possible life saving measure but as a duty on the part of the surgeon.

It is to be understood, from a pathological point of view, that there are only two ways in which a cancer of the ovary may be spread to other structures. One of these is through implantation of tumor fragments, the other is via the lymphatics and blood vessels and along the fascial planes. Before a papillary process or fragment of tumor can appear on the surface of an ovarian cyst, the tumor cells must have passed from the lining of the cyst through the wall and peritoneum. At first, or early, they are small granular excrescences which may occur on a localized area or in blotches over the surface of the malignant cyst. It seems to me that when the surface of an ovarian cyst has a grayish frosting or appears granular in blotchy areas, we should recognize that this conforms with one method of spread of the tumor cells and malignancy should be strongly suspected. Not only this, but care should be exercised in handling these tumors for fear of rubbing off papillae or granules and losing them in the peritoneal cavity.

Because of the possible spread of the tumor through the lymphatics, blood vessels and fascial planes, our exploration should include an examination of the mesosalpinx, the mesovarium, the round ligament and the broad ligaments. If there is induration or thickening of one or more of these structures at the base of the tumor, we also know that this conforms to the spread of malignant disease and that the suspicion of cancer should be very strong. I believe that when these conditions exist, the general peritoneal cavity should be walled off and the entire internal genitalia removed. A metastatic nodule in the groin or lumbar lymph nodes indicates that the cancer is inoperable.

It is unfortunate that we have only one tool in our armamentarium that is effective in cancer of the ovary. This, as implied, is radical early surgery. Late surgery is only palliative. Perhaps one reason why these tumors of the ovary are less sensitive to radiation is that they are very often highly differentiated. It is well known that the embryomas and other tumors less differentiated, such as the granulosa-cell tumors, are more sensitive, but even these may recur.

We had at the Worcester Memorial Hospital, from 1929 to 1937 inclusive, 50 cases of primary epithelial tumors of the ovary. This, of course, includes a number of benign tumors such as papillary cystadenoma and multiple cystadenoma. At my request, the sections of these cases were reviewed by our pathologist, Dr James P. Beck, with the idea of separating the definitely malignant tumors from this group. This was done, and it was found that there were only 13 malignant tumors. The criteria used in determining the malignancy were areas of adenocarcinoma in the wall of the cyst, mitotic fig-

ures, undifferentiation and atypicality of cells. It is seen that, of this group, only 26 per cent of our primary tumors are malignant. This is a much smaller percentage than the 55 per cent which Dr Meigs has found in his group of 250 cases. A reason for this discrepancy may be that we separated the malignant tumors from the epithelial cysts and primary tumors which occurred in the ovary, while Dr Meigs excluded the frankly benign ones before the series was compiled.

The outstanding points which Dr Meigs has striven to make clear to us are the early recognition of carcinoma of the ovary, exploratory laparotomy and early radical surgery.

DR. JAMES R. MILLER, Hartford, Connecticut. I have been going over the material at the Hartford Hospital since 1916 and no one who has not delved into material of that kind appreciates what an enormous amount of work Dr Meigs has put together in this study.

One point that he did not touch upon, which is perhaps outside of his paper, is a reference to sarcoma of the ovary. It has been definitely shown that most of the patients with so-called sarcomas have actually had granulosa-cell tumors, and under that diagnosis have been cured of a benign lesion. We have, however, had a large number of granulosa-cell tumors which have been malignant, nevertheless, I think it is quite proper to take out all these differentiated tumors from the group of ovarian carcinomas.

DR. EDWARD H. RISLEY, Waterville, Maine. I should like to ask Dr Meigs if he will not state his attitude toward postoperative radiation of these tumors.

DR. MEIGS (closing). I believe that if the oriental cake can be removed successfully and easily, and if there is no evidence of extension of the growth over the parietal peritoneum, it should be removed, or if the surgeon thinks that he has the tumor all out except that in the omentum, it ought to be removed, otherwise, I do not believe it is worth while.

To answer Dr Rusley's question about x-ray treatment, I believe that it will eventually prove to be of extreme value. Patients who have cancer of the cervix at the Pondville Hospital all have x-ray treatment before they are given radium. I have been studying the slides after that treatment, and there is no question but that this treatment changes the tumor remarkably. We have found that if tumors show radiation reaction in the stroma and in the epithelium of the cancer following x-ray, the chances of cure are good, but if the tumor shows no microscopic evidence of change, the chances are very poor.

I know that x-ray treatment can change epithelial lesions in the cervix, and therefore it ought to be used in epithelial growths in the peritoneal cavity. My objection is to the method of treatment, and I believe that roentgenologists will soon be able to deliver diffuse and wide spread radiation so as to cover most of the abdomen. The surgeon should show the radiologist where the tumor masses and their extensions are. The surgeon takes out a tumor and says there are peritoneal metastases, and the x-ray department irradiates the abdomen. It is up to us surgeons to talk the proposed treatment over with the roentgenologist and see if a method cannot be established whereby the abdomen can be more fully and completely treated. We should be able to salvage a few more of these patients.

## LIPODYSTROPHIA FACIALIS\*

### Case Report

RUBIN GURALNICK, M.D.† AND HYMAN GREEN, M.D.‡

BOSTON

IN REPORTING 6 cases of lipodystrophy Parmelee<sup>1</sup> reviews the literature extensively up to the time of his report, according to him, Coates<sup>2</sup> in 1925 summarized 63 such cases up to that year. The latter defines lipodystrophy as a disease characterized by a loss of subcutaneous fat from the face and upper portion of the body without any apparent ill health. He states that the disease affects children chiefly between the ages of five and eight, the ratio between girls and boys being 2:1. Parmelee states that the chief characteristics in his 6 cases were the thin, cadaverous facies and emaciation of the upper trunk, while the rest of the body appeared either normal or better than normal. There was no assignable cause for the malady in any of his patients, and the general health of all was very good. The children, being rather

young, displayed no abnormal mental complexes as a result of their abnormal appearance. Parmelee states that there is a multiplicity of theories to explain the local character of the fat absorption but that these only serve to emphasize the lack of knowledge as to the etiology.

Campbell<sup>3</sup> concurs with Coates in the definition of the disease as well as in its main characteristics. In his series of cases, also, girls were predominant. According to him, the loss of fat in girls is peculiarly confined to the face and trunk as far down as the iliac region, while the breasts and the region below the ilia show a well-defined hypertrophy, as though compensatory in nature. In boys, on the other hand, the characteristic loss of subcutaneous fat seems to be confined to the face only, the rest of the body remaining normal. He reiterates that the general health of the patient seems to be remarkably unaffected, and rules out the possibility of a pituitary disturbance as being the etiologic factor, because of the curious limitation of the ab-

\*From the Pediatric Department, Beth Israel Hospital, Boston.

Visiting pediatrician, Beth Israel Hospital.

sorption of fat to well-defined areas. It would not be possible, he argues, for the anterior portion of the pituitary body, which apparently has to do with the control of fat distribution, to be so selective in its control as to affect only certain areas of the body surface. He cites a case in which, besides the characteristic appearance peculiar to the disease, the patient exuded an abnormally strong body odor, and from this he argues that an overactivity of the sebaceous glands of the face and trunk may have something to do with the peculiar loss of fat in these parts only. To substantiate his theory, he calls attention to the fact that the sebaceous glands of the lower portion of the body are, as is well known, very inactive, and that as a result of such inactivity this part of the body is not affected in this disease.

Thannhauser<sup>4</sup> in his work on lipid diseases calls attention to Simons's disease (not to be confused with Simmond's disease), which is characterized by the localized fat absorption just described, and which Simons<sup>5</sup> himself called *lipodystrophia progressiva*. In 1911 Simons reported a number of such cases without known etiology, Meyer,<sup>6</sup> in reviewing Simons's cases, was inclined to believe that the etiology lay in a segmental trophoneurosis, although he could demonstrate no local changes in the nerves. He described a case of a woman who appeared very emaciated facially, yet whose breasts and the lower portion of whose body seemed in better condition than the average.

From this it may be seen that although the writers mentioned all agree in the general description of the disease, the etiology nevertheless remains obscure. This makes it rather a distinct entity, and on closer examination of all the facts presented, one should find no difficulty in differentiating this disease from the following:

**Simmond's disease**—a syndrome of hypophyseal cachexia with a train of symptoms quite distinct from any other disease.

**Facioscapulohumeral muscular dystrophy**—characterized by a wasting of the muscles but not of the fat tissue, and quite progressive in character.

**Progressive muscular atrophy**—differentiated along the same lines, and chiefly familial in character.

**Progeria**—senile appearance in children, together with other signs of senility which are very distinct.

**Malnutrition and cachexia**—a lack of adiposity in general, least of all in the face, the underlying cause of which can usually be easily detected.

#### CASE REPORT

D. P., an 8-year-old girl, was brought to the Out Patient Department of the Beth Israel Hospital on February 25, 1938, because of 'thinness of face.' Her present illness had begun when she was 4 years old, and it had become increasingly noticeable that her face was getting thin. This was more apparent because up to the age of 4 she was considered to be a rather plump child (Fig. 1).

Her sister could not recall any unusual illness preceding this sudden change in the child's appearance, nor was there any noticeable change in the child's behavior, habits or appetite. It was also observed that while the face was getting thin it also took on a peculiar whitish appearance. The patient's condition continued to become progressively worse for 2 years, and on the advice of the family doctor a tonsillectomy was performed. Since then there had been no further change in the facial appearance. Her appetite remained good and she got an adequate and fairly well balanced diet. Her habits were

Figure 1

good, and she generally got about 11 hours' sleep. She was active, helped with the housework and took part in the usual outdoor activities of children. She displayed no weakness on walking or during play, and got along well with her playmates. She did not seem to suffer from any complexes due to her facial appearance and was mentally alert, and her school rating was good.

The patient was the tenth of a family of eleven children. She was born at full term and of normal labor. At birth she appeared healthy and of average weight. She was breast fed for a short while, and was then put on a Dextrin Maltose milk formula. The addition of solid foods followed in due course. She had always had a sufficient amount of cod liver oil and orange juice in infancy, and so far as known her development was not out of the ordinary. She walked and talked at the expected time and was considered an average healthy child. She had had measles, chickenpox and whooping cough before she was 2 years old. She also had had a few 'slight colds.' At the age of 6 her tonsils and adenoids were removed because of her appearance, as previously stated. She entered kindergarten at the age of 4 and had been regularly promoted.

The mother died of pneumonia at 41 when the patient was a little over 1 year old. The father died 2 years previous to admission at 52, of a tumor of the stomach. One

brother died of accidental drowning, and another of pneumonia in infancy. There were no miscarriages. There were four brothers and four sisters, all apparently in good health except one brother, who was totally blind as the result of an accident. The family lived in a tenement flat cared for by the oldest sister, assisted by a state agency. The sleeping quarters were adequate and clean, and the food seemed to be adequate. There was no history of tuberculosis and none of allergic or mental disease. All the brothers and sisters were normal in weight and appearance, and there was no record of muscle dystrophy in any member of the family. The father and mother both came from Italy and married in this country, and all the children were born in or around Boston.

The patient was 49½ inches in height and weighed 60 pounds, a little above the average for her age. She was

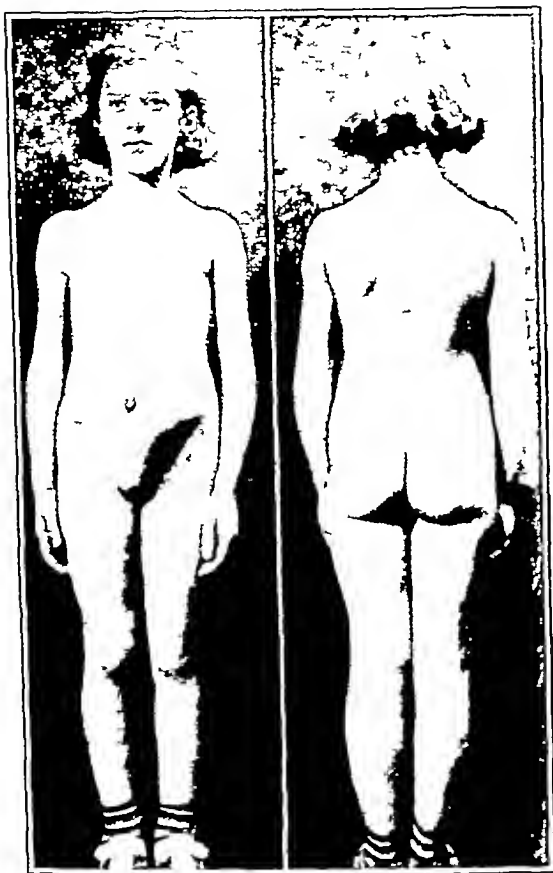

Figure 2.

bright and co-operative. The striking thing about her appearance was the drawn, thin face, with hollow cheeks and a peculiar pallid hue. The cheekbones were prominent and the skin lay in deep folds along the corners of her mouth, giving her a senile appearance. This thinness of face extended to the neck and slightly below the clavicles. On palpating the face, one was impressed by the thinness of the skin and the total absence of fat beneath it. When the patient was told to pucker her mouth the masseters stood out as small, thin bundles without any roundness of the surrounding tissue. On smiling, the skin wrinkled while the muscles around the mouth stood out grotesquely as in very debilitated old people.

The rest of the body appeared rather plump, particularly the pectoral regions and from the pelvic girdle down. The secondary sex characteristics, however, showed no precocity, and with the exception of somewhat poor dental development and slight icteric tinge of the sclera the rest of the physical examination appeared to be negative. (See Figs 2 and 3)

The red-cell count was 4,280,000, and the hemoglobin 75 per cent. The white-cell count was 8600, with 52 per cent polymorphonuclears, 38 per cent large lymphocytes, 8 per cent small lymphocytes, 1 per cent eosinophils and 1 per cent basophils. The achromia was 1+. The blood Wassermann and Kahn tests were negative. The blood cholesterol was 173 mg per cent and the blood calcium 10.5 mg per cent. The nonprotein nitrogen was within normal limits. The basal metabolic rate was +2 per cent. The sugar-tolerance test was as follows: fasting 74 mg, first hour 111 mg, second hour 77 mg and third hour 47 mg per cent. The urine was negative. An x-ray

Figure 3

of the skull showed no abnormalities of sutures or sella, and an x-ray of the ossification centers showed development consistent with the patient's age.

#### SUMMARY

This case of lipodystrophia facialis in an eight-year-old girl is of interest because of its comparative rarity, as well as for the ease with which it may be overlooked. As may be seen from the description of the case itself, as well as from the brief review of pertaining literature, the condition is generally characterized by a gradual disappearance of the subcutaneous fat from the face and trunk down to the pelvic region, with some hypertrophy of the fat of the rest of the body. The general health remains remarkably unaffected. The disease affects children chiefly between the ages of four and eight and usually becomes stationary at about that age. Girls are the chief victims of this peculiar disease. The etiology is

sorption of fat to well-defined areas. It would not be possible, he argues, for the anterior portion of the pituitary body, which apparently has to do with the control of fat distribution, to be so selective in its control as to affect only certain areas of the body surface. He cites a case in which, besides the characteristic appearance peculiar to the disease, the patient exuded an abnormally strong body odor, and from this he argues that an overactivity of the sebaceous glands of the face and trunk may have something to do with the peculiar loss of fat in these parts only. To substantiate his theory, he calls attention to the fact that the sebaceous glands of the lower portion of the body are, as is well known, very inactive, and that as a result of such inactivity this part of the body is not affected in this disease.

Thannhauser<sup>4</sup> in his work on lipoid diseases calls attention to Simons's disease (not to be confused with Simmond's disease), which is characterized by the localized fat absorption just described, and which Simons<sup>5</sup> himself called *lipodystrophia progressiva*. In 1911 Simons reported a number of such cases without known etiology, Meyer,<sup>6</sup> in reviewing Simons's cases, was inclined to believe that the etiology lay in a segmental trophoneurosis, although he could demonstrate no local changes in the nerves. He described a case of a woman who appeared very emaciated facially, yet whose breasts and the lower portion of whose body seemed in better condition than the average.

From this it may be seen that although the writers mentioned all agree in the general description of the disease, the etiology nevertheless remains obscure. This makes it rather a distinct entity, and on closer examination of all the facts presented, one should find no difficulty in differentiating this disease from the following:

Simmond's disease—a syndrome of hypophyseal cachexia with a train of symptoms quite distinct from any other disease.

Facioscapulohumeral muscular dystrophy—characterized by a wasting of the muscles but not of the fat tissue, and quite progressive in character.

Progressive muscular atrophy—differentiated along the same lines, and chiefly familial in character.

Progeria—senile appearance in children, together with other signs of senility which are very distinct.

Malnutrition and cachexia—a lack of adiposity in general, least of all in the face, the underlying cause of which can usually be easily detected.

#### CASE REPORT

D P, an 8-year-old girl, was brought to the Out Patient Department of the Beth Israel Hospital on February 25, 1938, because of 'thinness of face'. Her present illness had begun when she was 4 years old, and it had become increasingly noticeable that her face was getting thin. This was more apparent because up to the age of 4 she was considered to be a rather plump child (Fig 1)

Her sister could not recall any unusual illness preceding this sudden change in the child's appearance, nor was there any noticeable change in the child's behavior, habits or appetite. It was also observed that while the face was getting thin it also took on a peculiar whitish appearance. The patient's condition continued to become progressively worse for 2 years, and on the advice of the family doctor a tonsillectomy was performed. Since then there had been no further change in the facial appearance. Her appetite remained good and she got an adequate and fairly well balanced diet. Her habits were

Figure 1

good, and she generally got about 11 hours sleep. She was active, helped with the housework and took part in the usual outdoor activities of children. She displayed no weakness on walking or during play, and got along well with her playmates. She did not seem to suffer from any complexes due to her facial appearance and was mentally alert, and her school rating was good.

The patient was the tenth of a family of eleven children. She was born at full term and of normal labor. At birth she appeared healthy and of average weight. She was breast fed for a short while, and was then put on a Dextrin Maltose milk formula. The addition of solid foods followed in due course. She had always had a sufficient amount of cod liver oil and orange juice in infancy, and so far as known her development was not out of the ordinary. She walked and talked at the expected time and was considered an average healthy child. She had had measles, chickenpox and whooping cough before she was 2 years old. She also had had a few slight colds. At the age of 6 her tonsils and adenoids were removed because of her appearance, as previously stated. She entered kindergarten at the age of 4 and had been regularly promoted.

The mother died of pneumonia at 41 when the patient was a little over 1 year old. The father died 2 years previous to admission at 52, of a tumor of the stomach. One

submitted to inoculation with syphilitic blood. After the incubation period one of them developed secondary manifestations. He died in 1922.<sup>3</sup> The other two escaped infection.

In order to ascertain how blood transfusions were being performed throughout the country, Levine and Katzin<sup>4</sup> sent a questionnaire to about seven hundred hospitals. Only three hundred and fifty of these responded, and many questions were answered vaguely. An inquiry as to the percentage of cases in which a serological test for syphilis was done previous to transfusion was unanswered by one hundred and thirty-six hospitals. Ninety-one stated that such tests were regularly omitted, reliance being placed on a routine test performed about every six months. Information concerning examination of the donor was unfortunately not covered by the questionnaire. According to Rein et al.,<sup>5</sup> in 2 per cent of the hospitals in the United States donors report for a blood test only once a year. Only 3 cases of syphilis were reported among the accidents following transfusion—obviously an unbelievably small number. Rein et al. stated that the known cases of transfusion syphilis numbered 68.

Syphilis from transfusion is unquestionably a most deplorable accident. That there should be such a large number of cases, a fact which is not published but is well known, is without justification. As is true of syphilis contracted in other ways, the eradication of transfusion syphilis is impossible, but its frequency can undoubtedly be reduced to a minimum. To this end, all cases should be punctiliously reported instead of being consigned to a pious oblivion. Health authorities should give wide publicity to such cases among the members of the medical profession, and should warn them periodically of the possibility of transfusion syphilis, reminding them that even the ex-

istence of an emergency is not a valid excuse for their occurrence, since a Kline microscopic test can be done in an hour and a Hinton test in one and a half hours. Those in charge of operating rooms should be requested to keep in view and attached to transfusion apparatus reminders such as the following: "Have the donor and the recipient been given a blood test for syphilis today? Has the donor been questioned and carefully examined for syphilitic manifestations?"

Just as on the highway good brakes and proper operation of an automobile represent a very small accident hazard, so a properly performed blood transfusion should represent a minimum hazard. Accidents will happen, but they should be limited to cases where it is impossible to avoid them.

#### SUMMARY

A case of transfusion syphilis is reported, in order to stress the need of serological tests and careful examination of the donor for syphilitic manifestations immediately before every performance of blood transfusion.

The posting of warning notices in operating rooms is suggested in order to reduce the incidence of transfusion syphilis to an unavoidable minimum.

unknown and the theories are conflicting and not convincing. Wasting diseases can be differentiated from it by the finding of a definite etiologic factor. Systemic treatment is of no avail. An increase in diet results only in an increase in the total avoirdupois without in any way changing the patient's appearance. The cosmetic correction of the peculiar facies by injection of paraffin into the subcutaneous tissues is not advisable because

of the danger inherent in the use of a foreign substance.

## TRANSFUSION SYPHILIS

FRANCESCO RONCHESE, MD\*

PROVIDENCE, RHODE ISLAND

THE performance of a blood transfusion without previous physical examination and a blood test for syphilis, although plenty of time in which to do them is usually available, seems to be a common practice. More than once I have questioned patients about blood tests, and have received answers such as the following: "I never had a blood test, but my blood must be all right since I gave it to a friend a few months ago. I was only typed and there was no emergency."

If this subject is brought up in private conversation among doctors, it is generally admitted that everyone knows of transfusion syphilis, but there is an evident desire to avoid having the fact become public.

The case of transfusion syphilis here reported is presented in order to call the attention of physicians to this matter. It shows what narrow escapes there may have been in the past from the accidental transmission of syphilis, in cases where reliance was placed on a donor's statement of good health or on a Wassermann test taken months before and so absolutely worthless. Klauder and Butterworth<sup>1</sup> investigated the medicolegal aspect of the subject and found that verdicts had been returned against doctors who made transfusions without previous serological tests for syphilis.

## CASE REPORT

A 13-year-old boy examined on April 6, 1938, presented a maculopapular rash consistent with secondary syphilis. His blood Wassermann reaction was 4+ with both antigens. The approximate time of onset of the rash was the 1st week of March, 1938. It was not noticed whether it appeared first on the legs or on the body. It eventually appeared on the entire body and remained evenly distributed.

According to the patient's mother he was operated on November 30, 1937. The history showed that he was in

a state of extreme cachexia, so that a fatal termination was momentarily expected. On December 2 he received an emergency blood transfusion (citrated) from a 20-year-old friend of the family. The donor's blood was typed but he was not given a physical examination. He was carrying a penile sore at the time of the transfusion. About January 1, 1938, he developed secondary manifestations of syphilis and gave a positive Wassermann reaction. He apparently never showed a rash. The chancre persisted for 6 weeks. At the end of April, 1938, he was symptom free, but still gave a positive Wassermann reaction.

The patient had a negative Wassermann reaction on December 8, 1937. His mother and father each had a negative test on April 11, 1938. Toward the end of March, previous to any antibiotic therapy, he was up and about and had gained 40 pounds in weight. The patient's rash responded quickly to treatment with neoarsphenamine, administered intravenously.

From the data given above one can hardly doubt that syphilis was transmitted with the transfusion, which had been given without questioning the donor about sexual exposure, and without giving him a physical examination or a serological test for syphilis. In this case, however, even if a Wassermann test had been done on the donor's blood it might have brought a negative response, since the donor may have been in the preserological stage of infection. Moreover, even if previous to the transfusion he had been questioned about sexual exposure he could have denied it, and on examination what remained of the chancre might have escaped observation. The only conclusion that can be reached in this case, strange though it must appear, is that a pint of fully active syphilitic blood put a dying patient on his feet.

The infectiousness of syphilitic blood was reported for the first time in 1862.<sup>2</sup> To solve the problem of the transmissibility of syphilis by the blood, then under debate, three Italian physicians

emia One had eclampsia and the remaining 9 showed albuminuria, edema, elevation of blood pressure, some retention of nonprotein nitrogen and varying grades of anemia Seven cases showed the objective signs of a disturbance in the placenta or membranes, such as vaginal bleeding and premature rupture of the membranes Three mothers

each contained areas of infarction showing acute necrosis The infant of the eclamptic mother was stillborn and the placenta showed no marked gross changes There were two areas of hemorrhage each measuring about 2 cm in diameter The microscopic changes were those of infarction and acute necrosis

showed both toxemia and vaginal bleeding in the late prenatal period As a rule the labor was not difficult, and from the necropsy findings no evidence of trauma was discovered

Three of the mothers of stillborn infants had toxemia without vaginal bleeding, but the placenta of each showed infarctions with acute necrosis The mothers of the remaining 4 stillborn infants had vaginal bleeding before the onset of labor Only two of these placentas were examined, and

The mothers of the 2 extremely premature infants (Cases A38-20 and A38-24) presented no symptoms of toxemia, but both had vaginal bleeding and showed evidence of premature separation of the placenta One infant was liveborn, living for fifteen minutes postnatally, and the placenta showed no abnormal change, either grossly or microscopically There were 6 liveborn premature infants Three of the mothers had toxemia, 2 had vaginal bleeding and 1 had both

## DEATH IN NEWBORN AND STILLBORN INFANTS\*

JAMES S P BECK, M D †

WORCESTER

IN a small series of 25 cases of death in infants, varying in gestation age from five to nine months, and in which there were available the postmortem material and clinical data, it was found that the cause of death in 64 per cent was traceable to intrauterine disturbances other than those related to the fetus or to difficult delivery. This

## MATERIAL

The tissues consisted of the postmortem material accumulated in the past fourteen or fifteen months from cases admitted to the Memorial Hospital, and from others coming into the laboratory. The cases were taken in chronological order. Most of these infants were born in the hospital, so that the pre-

formed the largest as well as the most interesting group. The remaining 36 per cent consisted of congenital malformations incompatible with extrauterine life (12 per cent), injuries due to difficult labor (20 per cent) and syphilis (4 per cent). While the number of cases is small, the findings seem to indicate accurately where the mortality of infants of this age is generally highest.

Along with the postmortem material a study of the changes in the placentas of most of the cases has been made, and correlated with the clinical

and confinement histories were readily available. A few were admitted to the hospital from immediately outlying districts, shortly after birth. Their histories, though adequate, were brief. One of the infants having multiple congenital anomalies (Case A38-7, Table 1) was an outside case possessing medicolegal interest, the body being brought to the laboratory for postmortem examination. The small series therefore includes only postmortem cases in which the cause of death was directly associated with pregnancy and labor.

cal data of the prenatal and confinement records. This correlation has been stimulating, and has afforded a better understanding of the anatomic findings in the placentas and bodies of the infants. Deaths due to congenital anomalies and injuries sustained during difficult labor and due to specific infection† will not be discussed. They are summarized in Tables 1 and 2.

\*From the Pathological Laboratory of the Memorial Hospital Worcester Massachusetts.

†Pathologist Memorial Hospital

‡The single case of syphilis does not appear in the tables. The spirochetes were found in the ascitic fluid by dark field illumination and in the tissues by Levaditi's stain. The blood Hinton tests were positive.

In Table 3 are grouped the 16 cases selected for discussion. Among them are 7 stillbirths (28 per cent) and 9 liveborn infants (36 per cent) whose postnatal life averaged nine and a half hours. The shortest postnatal life was fifteen minutes in a premature infant weighing 20 ounces. The longest was thirty-six hours in an infant weighing 5 pounds, 4 ounces. Clinically there were in every case objective prenatal symptoms pointing directly to a disturbance in the placenta or to the systemic diseases characteristic of pregnancy.

Ten of the 16 mothers had some type of tox-

toxins, drugs, abnormal quantities of metabolites or alterations of the protein or mineral balance are present in the maternal blood some of the substances or alterations may be present in the fetal blood. A diminished carbon-dioxide combining power in the fetal blood (as inferred from a similar change in the maternal blood before labor) may be reflected in fetal muscular weakness and hence the respiratory efforts after birth may be weak. In the case of drugs the stimulative or depressive effect on nerve tissue is known. Hypnotics and sedatives reach the fetal blood through the placenta and may depress the respiratory center.

From the standpoint of morbid anatomy there are few lesions distinctive of such chemical injuries. Acute venous engorgement of the viscera with varying degrees of edema of the organs and tissues in general, occasional pleural and abdominal effusion, ecchymotic hemorrhages in the epicardium, pleura, thymus, meninges, peritoneum, and so forth, are the usual associated anatomical findings. Whatever the contributions to these changes are from the effects of drugs, toxins or certain injuries due to trauma, they cannot be precisely separated from those due to anoxemia. Death in utero or shortly after birth, due to asphyxia, is accompanied by anatomic changes indistinguishable from those described and defined as due to shock<sup>2</sup> experimentally produced by toxins, drugs or trauma. It is a common observation among obstetricians that those newborn infants who have "blue asphyxia" have an excellent chance of recovery, while most of those having asphyxia pallida soon expire. The latter are the ones that have the clinical outward appearance of shock and form the majority of cases for postmortem examination. There is a need for differentiative clinical laboratory data on these cases to separate clinical shock from asphyxia.

In the microscopic sections the pink-staining precipitate seen filling the alveoli of the lungs in experimental shock or asphyxia has its origin in edema fluid rich in proteins. Pink staining precipitate is regularly seen in the partially inflated alveoli of the atelectatic lungs. The origin could be from edema fluid, but when the formed elements of the amniotic sac contents are present with it, some of the precipitate is undoubtedly due to the proteins of the amniotic fluid. Regardless of its origin, this fluid in the lungs produces a mechanical embarrassment to respiration. To withstand such anatomic changes demands a factor of safety in the cardiovascular-respiratory reflex mechanism. By this is meant that in non-atelectatic lungs, where the forces of congestion and edema are applied, the work of alveoli ren-

dered functionless by the fluid is accomplished by greater work on the part of the normal alveoli through hyperpnea, orthopnea and increased pulse rate. There is little or no such factor of safety in the atelectatic lungs of the living newborn because there is no excess of ventilating space to be used for compensatory purposes. Trivial as they may seem in relation to lungs without atelectasis, such elements as small masses of mucus, amniotic sac contents or edema fluid in the respiratory passages may well cause enough obstruction in a newborn infant already suffering from asphyxia to prevent the feeble efforts of respiration from becoming effective.

While these embarrassments to the inflow of air may be a contributing cause of death, the outstanding pathological finding is the asphyxia which the infant had before birth was complete. If the anatomical parts of the respiratory mechanism are normal, it may be assumed that the obstructing elements in the bronchi and lungs are there because of a preceding asphyxia. The anatomical findings of asphyxia and amniotic sac contents in the lungs may place the onset of the abnormal changes in the period of intrauterine life. Similarly, vaginal secretion and blood in the respiratory passages may place the date at the time of delivery. Hence, the causative factor may be found in the placenta and uterus or be associated with delivery.

*Aspiration of Amniotic Sac Contents* The determination of this condition is made by a microscopic examination of the lungs. The finding of lanugo hairs, large numbers of flat cells, and particles of vernix or granules of pigment or both (presumably from meconium) in the air spaces of the lungs simply indicates that the sediment of the amniotic fluid was aspirated before the amniotic sac was emptied. The importance of such findings has been questioned by some, and by others considerable importance is attached to them if associated inflammatory changes are present in the alveoli. Opinion differs as to whether these bodies can produce inflammatory changes, and it is considered by many that the inflammatory reaction in the lungs of the newborn is suggestive of aspirated vaginal secretion, particularly if bacteria are present. It is generally believed that the presence of large amounts of the sediment in the lungs is indicative of intrauterine asphyxia.

Theoretically there are two abnormal ways in which amniotic sac contents can be forced into the fetal respiratory passages. They may be forcibly aspirated as a result of an intrauterine agonal state during asphyxia, or may be forced into the lungs during uterine contractions. The latter con-

In the 16 cases only 2 of the liveborn infants weighed 5 pounds or more. They were regarded as full-term. The mother of one had signs of premature separation of the placenta and the infant was delivered by cesarean section, the placenta was not remarkable either grossly or microscopically. The mother of the other infant had toxemia. The placenta was not examined.

#### DISCUSSION OF ANATOMICAL FINDINGS

The anatomical findings in the bodies of the 16 infants were simple, and consisted of varying degrees of prematurity, atelectasis neonatorum, and aspiration of amniotic sac contents, associated anatomical findings of asphyxia and varying degrees of maceration of body tissues.

**Prematurity** Eleven infants (44 per cent) were premature by weight and measurement, but anatomically only 2 had lungs insufficiently developed to be compatible with life without placental circulation. One of these was stillborn, the other was a liveborn infant whose postnatal life was fifteen minutes. While prematurity may have been the immediate cause of death in the infant living for fifteen minutes, it could not have been the cause of death in the stillborn, although the anatomical findings were identical. (For comparison, see Cases A38-20 and A38-24.) Also the mothers of these two infants presented similar antepartum symptoms. The difference in the two cases lies in the timing of birth and in the placentas. The placenta of the stillborn showed an extensive pathologic change.

The primary cause of death may not be found in the bodies of premature infants. The search for a causative factor in such cases regularly includes an investigation of possible anatomic changes or other conditions responsible for premature birth. The cause of certain premature births may be the same as that producing intra-uterine fetal asphyxia. The objective maternal symptoms of varying degrees of toxemia of pregnancy, vaginal bleeding or threatened miscarriage show that there were disturbances in the functioning of the uterus and placenta sufficient to cause death of the fetus either before delivery or soon thereafter.

**Atelectasis and Associated Findings of Asphyxia** Every one of the infants in this series showed atelectasis. While its extent was not estimated it was observed that (except in the 2 cases of extreme prematurity) most of the alveoli were anatomically capable of inflation, and that generally the number of alveoli partially inflated was small in those infants who lived only a few hours after birth.

Clinically the infants were living in a state of partial asphyxia, and it may be assumed that the sustained asphyxia in part was due to a persistence of atelectasis. All newborn infants have atelectasis, and are normally endowed with a mechanism for overcoming it. This mechanism has been carefully studied by Wilson and Farber,<sup>1</sup> who have shown that the force necessary for the first effective inspiration is normally greater than all later ones. If the first inspiratory efforts are for any reason inadequate to inflate the first few alveoli, atelectasis will persist, and will continue to persist so long as this force is inadequate. The force of inspiration is a function of the respiratory mechanism involving anatomically the medulla oblongata, the phrenic and thoracic nerves, the muscles of the body wall and diaphragm and the bony structure of the thorax. Chemically it is affected as are other tissues by various injurious agents, and normally it is delicately sensitive to physical and chemical changes in the blood. In order for the mechanism to function it must be anatomically possible for very definite differentials to be established between the pressure in the thorax and abdomen and that of the atmosphere. The elements of the mechanism are recalled mainly for the purpose of showing the wide field in which abnormalities, largely responsible for persistent atelectasis, may be found in the bodies of newborn infants.

The bony defects and other gross anatomic abnormalities making impossible the establishment of adequate pressure differentials are determined by inspection and are congenital malformations.

It is well known that the rhythmic action and force of respiration are dependent on a normal neuromuscular reflex component and a normal chemistry of the blood. Traumatic injuries, inflammations and tumors of the brain and cord may weaken, alter or prevent the anatomical component from functioning. Muscular fatigue from prolonged ineffective inspiratory efforts in obstructed breathing results in a loss of force. These infants, without other assistance than removing the obstruction, may not be able to overcome atelectasis. The loss of muscular power associated with a severe anoxemia at the time of birth may result in respiratory efforts too feeble to start the process of alveolar inflation.

Important data concerning the chemistry of the blood of newborn infants are frequently reported, tending to indicate that there is a relation between the chemical constituents of fetal blood and those of the maternal blood. This implies that the principles of exchange of soluble substances are the same in the placental vessels as they are in the vessels elsewhere in the body. When bacterial

simple, making their value at present uncertain. It seems apparent, however, that there is a definite relation between these lesions and the abnormal physiologic changes causing death of the fetus in selected cases. The coexistence of eclampsia or toxemia of pregnancy and premature separation of the placenta with areas of acute necrosis is an example of the changes which lead to prematurity, persistent atelectasis and death in the fetus and newborn.

The clinical application of the disturbances in fetal circulation is in the evaluation of the grade of asphyxia in terms of fetal heart rate. Richardson<sup>4</sup> has evaluated the grade of asphyxia in varying degrees of premature placental separation by means of the fetal heart rate before and during delivery. He has shown that the fetal rate is 150 to 160 when one fourth of the placenta is separated prematurely, and when half the placenta is separated the rate reaches 170 to 190. When more than half is separated the heart begins to decompensate, the rate falling to 90 or 70 in the event that three fourths of the placenta is detached. This indicates that a drop in the rate after the rate has been rapid is an unfavorable sign. While Richardson's findings were related to premature separation, they indicate a principle applicable to embarrassment of fetal circulation in general. Such conditions as a tightly knotted cord, a prolapse of the cord and extensive infarctions destroying one fourth or more of the placenta usually affect the circulation and influence the fetal heart rate in a similar manner. Since the oxygenation of fetal blood becomes a function of the lungs after birth, the grade of obstruction to the inflow of air and the degree of atelectasis may be surmised from a similar alteration in the heart tones during the early neonatal hours. If the rate is slow immediately after birth it may indicate that decompensation is already at hand and that resuscitation procedures are immediately imperative. A few precious minutes of effective treatment at such a time may save the infant's life. On the other hand, if the process of overcoming atelectasis has begun and is progressive, there generally follows clinical improvement, and a gradual lowering of the heart rate in the course of a few days.

## CONCLUSIONS

The usual anatomical findings following deaths of the fetuses in utero and liveborn infants are discussed with reference to etiology. Our finding of a close relation between death and the complications of pregnancy or labor or both is in complete harmony with a recently reported<sup>5</sup> relation involving many hundreds of similar cases. The pathogenesis of the anatomic changes is considered with respect to immediate and contributing causes of death. In the discussion a few clinical differentiative tests and observations are indirectly suggested for early recognition of the chief pathologic changes in the living newborn. It is to be assumed from the discussion that all ailing prospective mothers should be brought as near to normal health as possible before delivery is allowed to start if the welfare of the infant is the more important. The blood in anemia should be brought to normal range, in acidosis or alkalosis the carbon-dioxide combining power of the blood should be adjusted to normal, in nutritional edema the blood proteins should be raised, and the toxemias of pregnancy should be treated with great care. Mothers having a history of abortions, miscarriages, stillbirths or premature births should be given vitamins and suitable hormones in the prenatal period in order to carry the pregnancy to term. Narcotics and anesthetics seem contraindicated in mothers below par. Finally, it is to be expected that infants of such mothers will do badly immediately following birth, and that the armamentarium for immediate and effective removal of foreign materials from the respiratory passages should be ready for use. Effective means for resuscitation should be made available for immediate use during the critical period just after the cord is severed. It seems logical to cleanse the nose and throat before the cord is cut, and to use resuscitation measures afterward.

dition appears physically unlikely if the fetus is suspended in the unruptured amniotic sac, because the increased external fluid pressure due to uterine contraction is equally distributed throughout all parts of the fetus, producing no differential in pressure and therefore no movement of fluid into the fetus. Such movement becomes possible, however, in breech or foot presentations with delivery. The nose and mouth may still be in the uterine cavity while the remainder of the infant's body is in the birth canal. Amniotic sac contents, pooled blood or mucus can then be forced into the respiratory passages during uterine contractions, because in this case the pressure of the contracting uterus is directed against the intrauterine content, squeezing the material into the nose and mouth, while the abdomen or thorax is subjected only to birth-canal pressure.

In our series about 50 per cent of the infants, both stillborn and liveborn, had amniotic sac contents in their lungs. This subject has been clearly discussed in a paper by Farber and Sweet.<sup>3</sup> They found amniotic sac contents in 88 per cent of 124 infants who lived from two hours to five weeks. In their paper the relation of the aspiration of this material to intrauterine asphyxia is shown, and the importance of such aspiration as an additional cause of respiratory embarrassment of the newborn is emphasized.

It is well, however, in this discussion to point out that such elements as small masses of mucus or aspirated amniotic sac contents, meconium, vaginal secretion or blood in the respiratory passages of newborn infants may cause a persistence of atelectasis and asphyxia in two ways. One is the mechanical embarrassment to the inflow of air to those alveoli in the field of obstruction. The other, theoretically, is the presence of interstitial edema and pleural effusion which is partly due to anoxemia.

Clinically, in the event of such obstructions, the chest may diminish in size slightly, instead of expanding, during the inspiratory phase (when the diaphragm descends and the abdomen swells owing to the force of atmospheric pressure on the non-rigid chest wall). During the expiratory phase the chest resumes its normal size as the abdomen diminishes proportionately. The chest wall is normally not so rigid immediately after birth as it is a few days later. In premature infants the rigidity is proportionately less than that in term infants, making this ineffective paradoxical breathing more noticeable. Since the negative intrathoracic pressure is most marked immediately above the diaphragm as it descends, the Litten sign is usually pronounced in cases of obstruction.

*Maceration of Body Tissue* This anatomic change is at times helpful in determining the approximate time of death before delivery of the stillborn. The degree of tissue maceration is more or less proportional to the time interval between death and delivery.

*Anatomic Changes in the Placentas* It seemed at the outset that the placentas should be examined grossly and microscopically with the same thoroughness that any surgical specimen receives. This became especially apparent when it was realized that this organ alone was acting for the lungs, gastrointestinal tract and kidneys of the individual whose body was presented for post mortem examination and whose major clinical life was spent in utero while this organ was functioning. Also, emphasis was placed on the placenta-uterus relation by such objective prenatal symptoms as toxemia of pregnancy, vaginal bleeding, threatened miscarriage, and so forth.

The anatomic changes consisted of infarctions, areas of necrosis, acute inflammatory changes in and about the villi and thromboses of maternal sinuses. Grossly the infarctions were characterized by fairly well-circumscribed yellowish or white areas, varying in size but averaging about 2 cm in diameter. Microscopically they were either masses of loose fibrin containing red cells and leukocytes, or were compact clumps of fibrillar hyaline material. Areas of necrosis are frequently associated with infarctions, resembling them in size but differing from them by having central cavitations which microscopically contain debris, leukocytes or poorly staining, partially autolyzed placental remnants. Many of these areas appear to be walled off by parallel strands of fibrin arranged in concentric fashion. Commonly a zone of compactly crowded poorly staining villi with pyknotic nuclei encircle these areas outside the wall of fibrin and leukocytes. Focal areas of necrosis may be found in the cotyledons, apparently unassociated with such infarctions and without a wall of fibrin. Sometimes the areas of necrosis consist of a mass of crowded necrotic villi seemingly held together by a coarse network of loose fibrin and leukocytes. When the villi show little necrotic change and are loosely arranged in the cotyledons, but contain neutrophils in their stroma and loose fibrin with leukocytes in the intervillous spaces, acute inflammation is implied. Inflammatory changes associated with small foci of necrosis and thrombosis of the maternal sinuses are seen in the decidua basalis. The frequency of these changes in the placenta and their relation to those found in the fetus may be seen in Table 3. These findings are few and

itself, and probably more in helping to localize the process

As soon as the results of bacteriological examination are ascertained, suitable treatment is instituted. If the organism is a streptococcus, sulfanilamide is administered. If it is a pneumococcus of the type having an antiserum, this form of therapy is given. The aftercare of these patients is of far more importance than the operative procedure. Morphine should be given in doses sufficient to relieve pain and to prevent restlessness. Adequate amounts of parenteral fluids must be given in order to combat dehydration and ketosis, but excessive amounts should be avoided on account of the danger of circulatory embarrassment. In cases calling for the use of sulfanilamide a daily or bi-daily blood examination should be made. It is common for this drug to cause a marked drop in the red-cell count and hemoglobin, which should be treated by transfusions. Abdominal distention is best relieved by Wangensteen suction and placing the patient in an oxygen tent with a high percentage of oxygen. The drain is removed when the temperature has reached normal, or a sinus tract has been definitely established, which is usually between the seventh and tenth days. This plan has not been followed for a sufficiently long time for us to feel certain of its merits, but our results so far are extremely encouraging. In 15 cases of idiopathic peritonitis treated in this manner, there were 3 deaths, a mortality of 20 per cent. Of these 15 cases, 8 were due to pneumococci and showed a mortality of 13 per cent, and 7 were due to streptococci and had a mortality of 29 per cent.

#### WILMS'S TUMOR (EMBRYOMA OF THE KIDNEY)

Embryoma of the kidney is a mixed tumor of great malignancy, of congenital origin, and usually manifests itself in the first two or three years of life. Clinically, these tumors seldom give symptoms other than the appearance of a rapidly growing mass in the region of the kidney. The general health of the infants is not affected even when the tumor has assumed enormous size. The urinary findings are only occasionally significant in showing red blood cells in the sediment and pyelograms are seldom more than suggestive of the diagnosis. The latter, however, can be correctly made, with very few exceptions, on the basis of the history and the physical examination. These tumors cause an extremely high mortality, but we believe that we have made some progress at the Children's Hospital by diverging from the common practice of other clinics.

A recent extensive review of the literature re-

veals that it has been a common practice in recent years to irradiate these tumors for a period of three to six weeks prior to performing a nephrectomy. In a recent publication on progress in urology by Colby<sup>1</sup> and in one by Kerr,<sup>2</sup> it is implied that this form of treatment is an advance. Familiarity with the results obtained by it and without it make this implication controversial. It is agreed by all observers, so far as I know, that embryomas of the kidney are extremely radiosensitive, and that they decrease in size very rapidly as a result of x-ray therapy. It is also agreed that no patient with a Wilms's tumor has ever been cured by irradiation alone. Recent careful microscopic examination of irradiated tumors shows that some cells are apparently destroyed, while some remain viable. The breaking down of tissue which results from x-ray therapy leaves viable cells in a position to be taken up more readily by the blood stream. Clinically, it is suggested that metastasis takes place earlier in patients who have received x-ray therapy than in those who have not. Furthermore, it is impossible to determine the time at which metastasis takes place or that it has not occurred during the period of regression under irradiation treatment. After a careful search in the literature last spring I was able to find reports of but 8 probable cures of embryoma of the kidney in children from other clinics. Of these, only 3 had received preoperative irradiation, while 5 had received none. When the 11 cases recently reported by the writer<sup>3</sup> are added to the 5 reported by others, it shows that in 19 cases reported as probable cures, 16 patients had received no preoperative irradiation. It would seem that until such time as x-ray therapy becomes more successful immediate operation is indicated and offers the best outlook for cure. This statement implies, of course, that the operation can be done with a low operative mortality. In the last ten years at the Children's Hospital, 30 patients with kidney embryoma have been operated on, with two operative deaths, a mortality under 7 per cent, and no patient has been regarded as inoperable on account of the size of the tumor. It is believed that the factors contributing to improved results are careful preoperative preparation, avoidance of unnecessary delay and operative technique. A transperitoneal approach is a distinct advance over the previously used posterolumbar incision. The renal pedicle and ureter are tied and cut before the kidney is mobilized. This minimizes the possibility of liberating tumor cells into the blood stream at the time of operation. Parenteral fluids and transfusion are used postoperatively when indicated.

## REPORT ON MEDICAL PROGRESS

## CHILDREN'S SURGERY

WILLIAM E LADD, M.D.\*

BOSTON

IN THIS paper no attempt will be made to cover all the advances in children's surgery, but rather a few subjects with which it is thought the general surgeon or practitioner may be less familiar than is the surgeon giving particular attention to this age group. In some of these conditions progress has apparently been made by diverging from the usually adopted methods of procedure.

## IDIOPATHIC PERITONITIS (METASTATIC PERITONITIS)

The term idiopathic peritonitis denotes an inflammation of the peritoneum due not to a spreading infection from inflammation of the appendix or fallopian tubes or from perforation of any of the abdominal viscera, but to a blood-borne infection involving primarily the peritoneal cavity. The organisms most commonly causing this type of peritonitis are the pneumococcus and the streptococcus. This condition is almost entirely limited to children, and perhaps, for that reason, is often inappropriately handled by those of limited experience in this age group. In recent years an attempt has always been made to differentiate preoperatively peritonitis of appendiceal origin and that of the idiopathic type.

This disease is characterized by an acute onset with abdominal pain and vomiting, and sometimes there is a history of an upper respiratory infection or diarrhea. The patient shows evidences of profound toxemia, prostration, a high temperature (104 to 105°F), a rapid pulse, a high white-cell count, generalized abdominal tenderness and muscle spasm. Idiopathic peritonitis is differentiated from peritonitis of appendiceal origin in that the tenderness becomes more general earlier in the course of the disease, the temperature is higher than is usual in appendiceal peritonitis, the white-cell count is higher, and there is greater and earlier prostration.

During the last fifteen years papers have been published giving a mortality of 65 to 100 per cent in this condition. In 1926 Lipshutz and Lowenburg<sup>1</sup> reported a mortality of 100 per cent, in 1930 a series of 51 cases was reported from the Children's Hospital<sup>2</sup> in Boston with a mortality of 65 per cent, in 1934 Donovan<sup>3</sup> reported a 75 per

cent mortality in pneumococcal peritonitis. During the period mentioned it has been a common practice to make a thorough exploration of the abdominal cavity for the origin of the peritonitis when it was found not to be the appendix. A good many years ago at the Children's Hospital it was recognized that this quest was in vain, and resulted not in the finding of the origin of the infection but in the speedy demise of the patient. We therefore adopted the policy of doing very little at the time of operation. The operation consisted solely in opening the abdomen, examining the appendix to make sure it was not the cause of the peritonitis and inserting a drain. This policy resulted in an improvement in results, so that in 1930 the mortality from both pneumococcal and streptococcal peritonitis was only 65 per cent. As a result of favorable reports on delaying the operation until such time as the localization might take place, we followed that policy for a number of years. This plan of treatment undoubtedly resulted in the saving of some lives that would have been lost by early operation. The drawback was that localization frequently failed to take place, and that many patients died during the period of delay. It must be recognized that in the child the length of the omentum relative to the size of the abdominal cavity is less than in later life, and for that reason, and perhaps on account of the greater activity of the child, localization of an inflammatory process in the peritoneal cavity takes place less frequently than in the adult. Delayed operation did not cause an improvement in our results—in fact the mortality rose to 72 per cent in a series of 54 cases. Recently we have swung back to early operation supplemented by chemical or serum therapy, as indicated. The present plan of therapy consists in making a small abdominal incision under novocain or nitrous oxide and oxygen anesthesia. As soon as the peritoneum is opened, the character of the pus and the appearance of the peritoneum make the diagnosis certain enough to allow the surgeon to avoid further exploration. Some of the pus is taken for the determination of the organism and a drain is inserted. The merits of the drain are, of course, open to argument, but from our clinical experience it is believed that it accomplishes some good in

\*Chief of the surgical service, Children's Hospital, Boston; clinical professor of surgery, Harvard Medical School.

they also resume a normal rate of physical and mental development much earlier and more completely than when they are treated by tapping and burr-hole drainage alone. It is believed that removal of the clot membrane, which is so often present, is as important as removal of the hematoma. These radical measures are often indicated in the treatment of this condition in infancy and childhood, while in the adult they would not be necessary or advisable.

#### FLUID NEEDS IN SURGICAL PATIENTS UNDER TWELVE

The maintenance of fluid balance is of paramount importance if good results are to be obtained in the surgery of this age group. The need for the administration of an adequate amount of fluid by the parenteral route is well recognized, and is even more important in the child than in the adult. There are certain difficulties in administering the proper amount to the small patient, and for this reason it is often inadequate. It must be pointed out, however, that bad as are the results from not giving enough fluids, there is danger of embarrassing the circulatory system in infants and children if too much is given by the parenteral route.

A good working rule is to make sure that the postoperative patient under six months of age receives and retains approximately 90 cc of fluid per pound every twenty-four hours. For example, an infant weighing ten pounds needs approximately 900 cc of fluid every twenty-four hours. If this infant in twenty-four hours takes and retains about 300 cc. of fluid by mouth and by rectum, approximately 600 cc must be added by the parenteral route. These figures are not absolute, but serve as a convenient and easily remembered guide. Important factors that must be considered in each case are the degree of dehydration at the time of hospitalization and the amount of daily fluid loss from vomiting, diarrhea or the use of the duodenal tube.

Saline is best administered under the skin. Normal saline is the most easily obtainable fluid and is useful, but Hartmann's solution, which is made up of sodium lactate in physiological saline, has certain advantages. The great safety factor in administering fluid under the skin is that it will not be absorbed faster than the patient can use it.

Glucose is often necessary to meet the needs of the patient. It should not be given under the skin. Glucose thus given in concentrations of 5 to 10 per cent does not result in a sufficient absorption to be of any practical value. If higher concentrations are used, there is great danger of causing a slough. Glucose may be administered by rectum but must be given slowly and in small

amounts in order to be absorbed, and the solution should never be over 10 per cent in strength.

Glucose solutions are best administered intravenously. In the infant and small child, it is often difficult to get into the vein unless proper apparatus is at hand and someone experienced in the technic of its administration is available. In giving intravenous fluids, 10 cc per pound of body weight for an infant under one year should be the maximum amount given at any one time, and even then it should be given slowly. For a patient from one to twelve years, 5 cc per pound should be the maximum amount given at any one time. The difficulty in administering intravenous fluid in this age group creates a great temptation to give a continuous intravenous drip after the manner so useful in adults. This method should be used with the utmost caution, as it is extremely difficult to avoid giving too much fluid too rapidly. If the drip is so arranged that it is slow enough so as not to embarrass the circulation, it may cease on account of thrombosis or collapse of the small vein used.

In any case where parenteral fluids are used for more than two or three days, the serum protein and the serum sodium should be determined daily. The serum protein should not go below 5.0 or 4.5 gm per cent. If it is allowed to do so, edema will surely follow. The serum sodium should not be allowed to go below 130 milliequivalents per liter. One must not wait for the dangerous clinical symptoms of right-sided heart failure or peripheral or pulmonary edema to appear. If so much fluid is given that edema and low serum protein result, wound healing is likely to be seriously interfered with.

The maintenance of adequate fluid balance is of paramount importance, but the danger of giving more fluid to these small children than they can utilize must always be borne in mind. As in the use of any form of drug therapy, an overdose may be more dangerous than an insufficient dose. Even though many patients at present probably receive less than an adequate daily amount of fluid, it is well that the dangers of overloading a small patient with fluid be emphasized.

# SURGICAL OBLITERATION OF THE PATENT DUCTUS ARTERIOSUS

Dr Robert E Gross at the Children's Hospital has opened a new field of surgical endeavor by operations on one form of congenital heart lesion. The immediate results of these operations are extremely gratifying and the future appears to be very promising.

The ductus arteriosus normally circumvents blood around the lungs while they are collapsed during fetal life. This vessel spontaneously closes within the first few months after birth, but if it should remain open an arteriovenous type of communication is thus established, which may impair the efficiency of the cardiovascular system. This abnormality causes only minor complaints during childhood or adolescence, but in adult life it often leads to serious and fatal complications, of which subacute bacterial endocarditis or cardiac failure are the commonest.

The foundations are laid in childhood for serious disease which may not become manifest until many years later. Blood rushing from the aortic arch into the pulmonary artery produces intimal thickening about the ductal orifice and in the pulmonary artery, which may later be the seat of bacterial vegetation. The vascular leak so increases the work of the left ventricle that cardiac reserve is reduced to a point where decompensation subsequently occurs. If these hazards in adult life are to be avoided, they must be warded off in childhood before permanent and irreparable damage has been done.

Working on this rationale, Gross<sup>7</sup> has developed a technic where the patent ductus can be exposed and surgically ligated. Studying post-mortem material and practicing the operative steps on dogs, a suitable approach by way of the left pleural cavity has been found which gives an adequate exposure of the aortic arch, pulmonary artery and ductus. The feasibility of such an operation has been demonstrated by successfully exploring and ligating the ductus in 4 patients without resulting mortality. These children, aged seven, eleven, seven and seventeen years, withstood operation remarkably well and did not develop any serious complications. Following operation, all the patients showed a marked diminution in the intensity of the previously overactive heart beat. In each case the precordial thrill disappeared. The loud murmurs which were so prominent before operation were reduced to minimal ones in 2 patients, and have completely disappeared in the other 2, which were treated by placing double ligatures on the ductus. In each case the low diastolic pressure which existed before operation rose by 25 to 35 mm of mercury to a permanently normal

level. In 2 cases there was no appreciable change in the size of the heart, but in the other 2 there were diminutions in its transverse diameter of 0.5 and 1.0 cm, respectively. Calculations of the blood flow were made in 2 cases by determining oxygen concentrations of blood samples taken from the aorta, ductus and pulmonary artery before and after ligation of the ductus. These studies showed that the peripheral circulation was greatly improved after ligation of the ductus, yet the work of the heart was greatly reduced.

The success of the operative procedure depends on recognizing this condition and differentiating it from other types of congenital heart disease. Surgery has much to offer those individuals who have a patent ductus arteriosus.

## SUBDURAL HEMATOMA IN INFANTS AND CHILDREN

Ingraham and Heyl<sup>8</sup> have in the course of the past year presented reasons for a more radical treatment of subdural hematoma in infants and children. This is of particular interest in view of the present tendency among neurosurgeons to treat this condition by extremely conservative measures. This seems to be due to the fact that adults respond very satisfactorily to conservative treatment. When infants and children are seen only occasionally in a group of patients most of whom are adults there is a natural tendency to treat all patients in the same way regardless of age. The chief reason for a different treatment in the younger group is the presence in the majority of cases of a definite clot membrane. If no membrane is present, drainage of the hematoma through burr holes is satisfactory at any age. If even a thin clot membrane is present over the surface of an infant's brain, however, it interferes with growth, and may result in cortical atrophy, because of the rapid rate of normal growth of the brain. This opinion has been verified at this clinic by the study of older children who were not treated radically or were not treated at all. In the adult brain where the size is fixed, the presence of a membrane is not nearly so vital as long as the fluid portion of the clot is removed.

It is of interest to note that subdural hematoma is a much commoner condition in infancy and childhood than is ordinarily supposed. A series of patients ranging from two months to six years in age were studied, and the authors now advocate radical treatment consisting of the removal of the hematoma and the hematoma membranes whenever their presence has been demonstrated through burr holes. This necessitates turning down bone flaps, a procedure which these patients tolerate well if they are properly handled. When so treated,

history in this particular case. Fever is common, often to a fairly high degree. The other aspect which strikes me is the fact that he had so few symptoms referable to the mass itself, or to the nodes. The history records specifically the absence of chest pains, of difficulty in swallowing or difficulty in breathing. Hodgkin's disease in the mediastinum is very frequently accompanied by rather severe symptoms from pressure either on the esophagus and trachea or on the various branches of the sympathetic chain.

I do not believe that either of these diagnoses fulfills the picture as it is given here and the third diagnosis which we certainly ought to consider is that of a primary lesion of the thyroid. It is fair to assume that he had an enlarged thyroid for a period of years. He did not show signs of hyperthyroidism. His weight is said to have remained steady. There is no mention of the other usual signs and symptoms of hyperthyroidism. He did have elevation of blood pressure and that is about all that can be even faintly suggestive of hyperthyroidism. If it is not hyperthyroidism then the various tumors of the thyroid must be considered. The one tumor which seems to fit all the various findings is the tumor classed as malignant adenoma. This may appear at an early age. The initial enlargement of the thyroid may remain without much change in size over some period of years and it eventually metastasizes. When it does, it may go by direct extension or by lymphatic invasion to the cervical nodes or into the mediastinum or by extension in veins into the lungs or bone. The tumor and its metastases may both be very highly differentiated and may suggest normal thyroid tissue. It is not a rapidly progressing and debilitating process such as adenocarcinoma or papillary carcinoma of the thyroid.

There are one or two symptoms which I attempted to fit into the picture. These are two attacks which were described as a warm sensation in the chest and abdomen and a feeling of faintness. These occurred eight to nine weeks before he came to the hospital. I thought that possibly a tumor located in the superior mediastinum in relation to the sympathetic chain might produce temporary pressure on it due to rapid change in size caused by hemorrhage or softening. These tumors of the thyroid are prone to cystic degeneration. A hemorrhage into the cyst might explain sudden change in size. The blood picture suggests infection. I tried to explain the slight leukocytosis and the slight amount of fever also on the basis of hemorrhage into a degenerative cyst or to necrosis. X-ray films show the deviation of the trachea. They do not show calcification in the region of the neck in

which the nodes are located, which one might expect with tuberculosis. The location of the mass is very high. There is no evidence of Hodgkin's disease elsewhere in the chest and the mass is above the hilar nodes and in a region which is perfectly comparable with a substernal thyroid mass. So I will rest with that diagnosis, a malignant adenoma of the thyroid with cervical and mediastinal metastases.

DR PAUL D. WHITE: Why could not these two attacks of faintness be paroxysmal tachycardia brought on by a full stomach plus the pressure?

DR TRACY B. MALLORY: It could be possible. Anatomically I cannot answer that.

DR FRANCIS M. RACKEMANN: Could the attack be due to pressure on the carotid since that is not far away?

DR WHITE: I think a warm sensation is more apt to indicate a fast cardiac action than a slow one.

DR RICHARD H. WALLACE: I sent him in from the tumor clinic and my original impression was that the nodes and the thyroid were distinct. I only saw him the one time in the tumor clinic. I thought that the firm matted nodes felt more like tuberculous ones than anything else, that the thyroid was distinct and that it probably was a simple colloid goiter. Dr. Richard Miller operated, I believe, and even after operation thought that it was a benign thyroid. The picture did not become clear until the slides were examined.

#### CLINICAL DIAGNOSIS

Neurofibroma of right neck

#### DR. MARKS'S DIAGNOSIS

Malignant adenoma of the thyroid

#### ANATOMICAL DIAGNOSIS

Papillary adenocarcinoma of thyroid

#### PATHOLOGICAL DISCUSSION

DR. MALLORY: The specimen which was removed consisted of a lobe of thyroid and a chain of enlarged cervical lymph nodes that measured 17 cm in length. There were about fourteen separate nodes that we counted making up the chain and also three or four separately submitted nodes which were not connected with the main chain. All the various specimens showed the same histologic picture. It was that of a papillary adenoma of the thyroid. We know that all these papillary adenomas are potentially malignant just as the rather similar looking tumors of the ovary are, although the usual histologic signs of malignancy may not be very obvious. These cases often present a difficult problem to both the surgeon and

## CASE 25131

### PRESENTATION OF CASE

A thirty-one-year-old single Canadian was admitted complaining of swelling of the neck and palpitation.

About fourteen years before admission the patient first noticed a swelling in the right side of his neck. This did not increase in size and produced no significant symptoms. There were no choking sensations and no pain. There was no progression in the size of the swelling for ten years preceding his admission. Four years ago he entered the Out Patient Department where he was advised to have his thyroid operated on. This he refused to do. Ten weeks before entry following a heavy meal he had a warm sensation in the chest and epigastrium, developed a feeling of faintness, which lasted about six or eight minutes, and broke out into cold perspiration. He entered an outside hospital where he was told that he was all right and was advised to eat light meals and take soda. A week later he had a similar episode about one hour after a light evening meal. Physical examination in the Out Patient Department on the following day showed enlarged nodes in the neck. These were thought to be tuberculous. An electrocardiogram was normal. The blood pressure was 130 systolic, 80 diastolic. He came to the tumor clinic of this hospital three weeks before entry, at which time the nodes in the neck were again noted. The left lobe of the thyroid was small but contained a 1-cm. nodule. The right lobe was the size of a small lemon, was firm, and was distinct from the lateral mass of nodes. His weight had remained normal. He had not had chest pain, dyspnea, night sweats, cough or dysphagia.

Physical examination showed a well-developed and nourished man in no distress. There was a large matted mass of non-tender nodes occupying the anterior and posterior cervical regions on the right except for the nodule in the thyroid. The right lobe of the thyroid measured 3 cm. in diameter and was firm. The nodes measured up to 2.5 cm. in diameter and were movable beneath the skin. The left side of the neck was essentially normal. Examination of the chest and abdomen

was negative. The blood pressure was 140 systolic, 100 diastolic.

The temperature was 99°F, pulse 80, respirations 24.

Examination of the urine was negative. The blood showed a red-cell count of 5,460,000 with 85 per cent hemoglobin, and a white-cell count of 11,000 with 86 per cent polymorphonuclears. A blood Hinton test was negative.

X-ray films of the chest showed displacement of the trachea to the left, apparently by a mass which lay in the right mediastinum and extended up into the right neck.

On the eighth hospital day an operation was performed.

### X-RAY INTERPRETATION

DR. AUBREY O. HAMPTON. There is a definite displacement of the esophagus and trachea to the left and thickening of the soft tissues in front of the trachea. I think we ordinarily call such a picture a tumor of the thyroid.

### DIFFERENTIAL DIAGNOSIS

DR. GEORGE A. MARKS. It seems to me the problem here is primarily whether to consider the mass of nodes separately or with the nodular thyroid as all part of one picture. The history is not quite clear as to just when the nodes were first found. The man is said to have had a mass in his neck for fourteen years and on examination in the Out Patient Department four years before his present entry a thyroidectomy was recommended. It was only when he returned here that any mention is made of the nodes, so I think it is fair to assume that the mass in his neck which was said to have been present fourteen years was probably the right lobe of the thyroid.

Going back to consider the nodes themselves, if they are to be considered separately, it seems to me the diagnosis lies between tuberculosis and lymphoblastoma, Hodgkin's disease or lymphosarcoma. The course since the development of the nodes might be consistent with tuberculosis although there is nothing striking in the physical examination in that regard. Tuberculous nodes are frequently tender, and episodes of tenderness may be associated with them, even though they do not go on to abscess formation. I think one of the striking aspects of the whole case is the fact that this man apparently was in such good health when he was admitted to the hospital. The course of tuberculous adenitis would probably hold episodes of fever. Hodgkin's disease, although it may be restricted to one side of the neck for a fairly long time, usually has a more debilitating course with relapses and remissions than is evidenced in the

history in this particular case. Fever is common, often to a fairly high degree. The other aspect which strikes me is the fact that he had so few symptoms referable to the mass itself, or to the nodes. The history records specifically the absence of chest pains, of difficulty in swallowing or difficulty in breathing. Hodgkin's disease in the mediastinum is very frequently accompanied by rather severe symptoms from pressure either on the esophagus and trachea or on the various branches of the sympathetic chain.

I do not believe that either of these diagnoses fulfills the picture as it is given here and the third diagnosis which we certainly ought to consider is that of a primary lesion of the thyroid. It is fair to assume that he had an enlarged thyroid for a period of years. He did not show signs of hyperthyroidism. His weight is said to have remained steady. There is no mention of the other usual signs and symptoms of hyperthyroidism. He did have elevation of blood pressure and that is about all that can be even faintly suggestive of hyperthyroidism. If it is not hyperthyroidism then the various tumors of the thyroid must be considered. The one tumor which seems to fit all the various findings is the tumor classed as malignant adenoma. This may appear at an early age. The initial enlargement of the thyroid may remain without much change in size over some period of years and it eventually metastasizes. When it does, it may go by direct extension or by lymphatic invasion to the cervical nodes or into the mediastinum or by extension in veins into the lungs or bone. The tumor and its metastases may both be very highly differentiated and may suggest normal thyroid tissue. It is not a rapidly progressing and debilitating process such as adenocarcinoma or papillary carcinoma of the thyroid.

There are one or two symptoms which I attempted to fit into the picture. These are two attacks which were described as a warm sensation in the chest and abdomen and a feeling of faintness. These occurred eight to nine weeks before he came to the hospital. I thought that possibly a tumor located in the superior mediastinum in relation to the sympathetic chain might produce temporary pressure on it due to rapid change in size caused by hemorrhage or softening. These tumors of the thyroid are prone to cystic degeneration. A hemorrhage into the cyst might explain sudden change in size. The blood picture suggests infection. I tried to explain the slight leukocytosis and the slight amount of fever also on the basis of hemorrhage into a degenerative cyst or to necrosis. X-ray films show the deviation of the trachea. They do not show calcification in the region of the neck in

which the nodes are located, which one might expect with tuberculosis. The location of the mass is very high. There is no evidence of Hodgkin's disease elsewhere in the chest and the mass is above the hilar nodes and in a region which is perfectly compatible with a substernal thyroid mass. So I will rest with that diagnosis, a malignant adenoma of the thyroid with cervical and mediastinal metastases.

DR PAUL D WHITE: Why could not these two attacks of faintness be paroxysmal tachycardia brought on by a full stomach plus the pressure?

DR TRACY B MALLORY: It could be possible. Anatomically I cannot answer that.

DR FRANCIS M RACKEMANN: Could the attack be due to pressure on the carotid since that is not far away?

DR WHITE: I think a warm sensation is more apt to indicate a fast cardiac action than a slow one.

DR RICHARD H WALLACE: I sent him in from the tumor clinic and my original impression was that the nodes and the thyroid were distinct. I only saw him the one time in the tumor clinic. I thought that the firm matted nodes felt more like tuberculous ones than anything else, that the thyroid was distinct and that it probably was a simple colloid goiter. Dr Richard Miller operated, I believe, and even after operation thought that it was a benign thyroid. The picture did not become clear until the slides were examined.

#### CLINICAL DIAGNOSIS

Neurofibroma of right neck

#### DR MARKS'S DIAGNOSIS

Malignant adenoma of the thyroid

#### ANATOMICAL DIAGNOSIS

Papillary adenocarcinoma of thyroid

#### PATHOLOGICAL DISCUSSION

DR MALLORY: The specimen which was removed consisted of a lobe of thyroid and a chain of enlarged cervical lymph nodes that measured 17 cm in length. There were about fourteen separate nodes that we counted making up the chain and also three or four separately submitted nodes which were not connected with the main chain. All the various specimens showed the same histologic picture. It was that of a papillary adenoma of the thyroid. We know that all these papillary adenomas are potentially malignant just as the rather similar looking tumors of the ovary are, although the usual histologic signs of malignancy may not be very obvious. These cases often present a difficult problem to both the surgeon and

the pathologist We have seen several cases in which a single nodule was removed from the neck as a biopsy and in which the question comes up, Is it metastasis to a lymph node or is it tumor of accessory thyroid tissue? We know, of course, that accessory thyroid tissue is particularly prone to develop into papillary cyst adenoma It may be very difficult to tell from looking at the sections whether one is dealing with primary tumor rising in accessory thyroid tissue or with metastasis from a primary focus in the thyroid itself In this case with the multiple gland involvement there is of course no question We have seen a number of these cases in this hospital and they all have run a very slow course such as this one has I do not see how we can tell how long the primary tumor has been present and over how long a period metastases have been developing I think one is prone to think of carcinoma of the thyroid as one of the few forms of cancer that frequently metastasizes by the blood stream, and we therefore forget the possibility that it not infrequently metastasizes via the lymphatics just as ordinary cancer does

DR MARKS Was the mass in the mediastinum a lower pole of the node?

DR. MALLORY The lower pole of the long chain of nodes

### CASE 25132

#### PRESENTATION OF CASE

A sixty-five-year-old, Austrian Hebrew building wrecker entered complaining of right chest pain, cough and blood-streaked sputum

One week before entry, at night, without previous cough, sputum or pain, the patient developed "grippe" and "cold" He had recovered ten days previously from a similar condition The last attack was soon followed by a sudden onset of sharp, stabbing pain in the right side, involving the right lumbar region, right axilla and right shoulder, associated with a cough productive of dark-red blood mixed with mucus Coughing increased the pain He had a temperature of 100°F but no chill His physician gave him a hypodermic for the pain and referred the patient to an outside hospital where he continued to raise dark-red sputum His chest was strapped, without relief The blood white-cell count ranged from 9000 to 13,000 The temperature ranged from 100.5 to 99°F, the pulse from 110 to 70 Respirations remained at 20 X-ray films of the chest showed density obscuring the right costophrenic angle, suggestive of fluid, and haziness of the left costophrenic angle There was also

some density of the right hilus in the region of the descending bronchus The heart shadow was normal An electrocardiogram showed no evidence of heart disease A chest tap yielded some bloody fluid which showed no tumor cells

The patient denied any weight loss, weakness or shortness of breath He had worked considerably with iron and steel

Physical examination on entry showed a well-developed and nourished man in no distress Examination of the heart was negative The blood pressure was 130 systolic, 80 diastolic Coarse intermittent rales were heard in the right base posteriorly and flatness and dullness were made out in the inferior lateral portion The remainder of the physical examination was noncontributory

The temperature was 98°F, the pulse 80, the respirations 20

The urine examination was negative The blood showed a red-cell count of 4,400,000 with 80 per cent hemoglobin, and a white-cell count of 9400 with 72 per cent polymorphonuclears The non protein nitrogen of the serum was 26 mg per cent The sputum was bloody and non-odorous

X-ray films of the chest showed a local area of density in the right costophrenic angle near the posterior axillary line, which was in contact with the pleura, moved with respiration and was convex toward the lung root There was hazy density around the shadow, which extended upward along the costophrenic angle and extended into the interlobar pleura The anterior costophrenic angle on the right side was shallow There was a dense line extending from the area of consolidation upward and medially toward the lung root There was no mediastinal shift and the remainder of the lung fields were clear

On the second hospital day the patient's condition remained essentially unchanged The following day the patient complained of substernal pain and soon thereafter shortness of breath Ten minutes later he was pale, cyanotic and showed definite air hunger The cervical veins were dilated The pulse was not obtainable at the wrist and there was no measurable blood pressure The lungs were clear The heart rate was very slow, the sounds feeble The patient's condition rapidly became worse and he died about forty minutes later

#### X-RAY INTERPRETATION

DR RICHARD SCHATZKI There is a lesion in the right lower lobe posteriorly An almost triangular area of consolidation is seen close to the pleural surface, with a linear area of increased density going toward the hilus I came in too late

to hear the history I should like to know how long that has been going on

DR. THEODORE C. PRATT It started a week before entry with cough, chest pain and hemoptysis and with bloody fluid in the pleural cavity

DR. SCHATZKI Of course that makes the diagnosis definite

#### DIFFERENTIAL DIAGNOSIS

DR. PRATT The differential diagnosis deals with those conditions that produce sudden hemoptysis with associated chest pain of pleural character. It seems to me we can rule out quickly any serious abdominal condition. No mention is made of symptoms or signs referable to the abdomen. Of the chest conditions producing sudden pain and hemoptysis several can be rapidly ruled out. There is no question of pneumonia, with or without empyema, in view of the symptoms and subsequent course. Tuberculosis can also be ruled out because of the essentially negative lung fields elsewhere and the negative past history. Pulmonary abscess or bronchiectasis can be ruled out for the same reason. He had no history of foul sputum and there is nothing in the clinical history to suggest it. A large mediastinal tumor which might erode through into the pleura or involve the lung can also be ruled out because of an apparently normal mediastinum by x-ray. An aortic aneurysm of the thoracic aorta I believe can be definitely excluded because of the completely negative examination so far as the heart and blood pressure are concerned. In addition an aneurysm in order to produce sudden death here would have to rupture into the pleura and produce sudden massive hemorrhage. His death as we see later was not due to sudden massive hemorrhage. In reading over the x-ray report and before I had seen the films I had considered the possibility of carcinoma of the lung, either of the bronchus or of the alveolar type, which we can now probably rule out on the basis of the x-ray alone. He had had no previous cough or dyspnea of long duration and no loss of weight and the fluid removed from his chest showed no tumor cells. Certainly carcinoma of the lung or of the bronchus is very unlikely.

That leaves us with only the diagnosis of pulmonary infarct secondary to a small embolus and followed later by a larger and fatal pulmonary embolus. This diagnosis seems to fit most of the data given. The only objection is that we are given nothing in the history or physical findings suggestive of deep phlebitis. There is no mention of tenderness of the legs or edema. If this were an operative case we could assume with a great deal of assurance that deep phlebitis existed either

in the iliac, femoral or popliteal vein. However, in this case, we have evidence of a definite infection of some type, perhaps respiratory, of about ten days' duration which might have been the etiologic factor for a phlebitis that occurred, possibly, in the pelvic veins. We shall assume that he did have phlebitis. The only other explanation for an infarct due to embolus would be that he had a thrombosis in his right heart or a primary thrombosis in the pulmonary artery, of which there is no evidence. So a pulmonary infarct representing the first episode seems reasonable. The temperature and the elevation of the white count fit in with that, as do his physical findings. The x-ray film, which is interpreted as showing a wedge-shaped area with the apex toward the hilus, also agrees, and I imagine that the extension over to the hilus is a collection of interlobar fluid. Would that be consistent?

DR. SCHATZKI This is a line that Dr. Hampton and Dr. Castleman are studying. It is probably due to atelectasis.

DR. PRATT The type of pain here is consistent with a pulmonary infarct of the right lower lobe and simply means diaphragmatic pleural irritation. I cannot explain the radiation into the lumbar region although I believe that it might occur. Certainly pleural effusion is consistent and with a large infarct can very well be blood stained. I believe, therefore, that the diagnosis is pulmonary infarct secondary to a small embolus occluding one of the pulmonary artery branches and followed by a fatal pulmonary embolus almost completely occluding the pulmonary artery, both emboli arising from the same source, probably a deep phlebitis.

DR. CHAMP LYONS This patient came in with a diagnosis of cancer of the lung, but on entry the brevity of his illness led us to believe he had a pulmonary infarct. We examined his extremities very carefully at the time and were unable to localize any definite signs of peripheral phlebitis.

#### CLINICAL DIAGNOSIS

Pulmonary embolism and infarction

#### DR. PRATT'S DIAGNOSES

Pulmonary infarct and fatal pulmonary embolus  
—both secondary to a deep phlebitis

#### ANATOMICAL DIAGNOSES

Pulmonary embolism, massive  
Pulmonary infarction, recent, right lower lobe  
Thrombophlebitis, organizing, right popliteal vein  
Arteriosclerosis, coronary and aortic, minimal

## PATHOLOGICAL DISCUSSION

DR TRACY B MALLORY The only point on which I should be tempted to criticize Dr Pratt's discussion is where he said something about phlebitis in the pelvic veins. That is possible but in the vast majority of cases with massive pulmonary emboli the phlebitis is found in the leg veins. This man had a large thrombus in the right popliteal vein, which was completely occluded. It obviously had at one time run almost all the way up the leg although the cephalad portions were broken off, which accounted for the fatal embolus found curled up in the main pulmonary artery and its right branch, so that it completely blocked the circulation of the right lung and partially that of the left lung. The lungs showed three areas of old infarction quite separate and distinct whereas I think in the x-rays you could not be certain of more than one.

DR PAUL D WHITE It is quite possible that the first attack, thought to be a cold, was the same thing.

DR MALLORY It is certainly possible, but it is equally possible it was a respiratory infection and that the phlebitis and all the rest were secondary to it. I do not see how we can answer that one way or the other. It is very common at autopsy to find multiple infarcts where the x-ray has been able to show only one or two of them. In the series that Dr Castleman and Dr Hampton have been studying recently, it is of interest that 40 per cent of all pulmonary infarcts come from cases from the medical wards that have never had a surgical operation. One has always been inclined to believe that pulmonary embolus is primarily a surgical complaint.

DR WHITE How many of the 40 per cent gave no clinical evidence of phlebitis?

DR MALLORY I should say at least 80 per cent. It is the exceptional case that shows definite evidence of phlebitis, yet in almost every case we

have found a primary phlebitis in the leg veins, certainly in all the cases of massive embolism and even in most of the cases with small infarcts.

A PHYSICIAN Recent cases from the Mayo Clinic indicate that when phlebitis makes itself known clinically the danger is essentially over.

DR MALLORY I should think that was very probably true. This is a type of case one sees all too often and should be a challenge to the medical profession. A patient who has had one pulmonary embolus evidenced by a demonstrable infarct is certainly in danger of subsequent ones, and perhaps a massive fatal one as in this case. It seems as though in the time interval which usually intervenes we ought to be able to advise something that would minimize the danger. As yet we have absolutely nothing to offer.

A PHYSICIAN One could tie off the affected veins if one knew where they were.

DR MALLORY There is practically never any clinical evidence of thrombosis.

DR WHITE I have had three patients this year whose veins I have had tied off.

DR MALLORY What has been the result, from the point of view of circulation?

DR WHITE It has been good.

DR MALLORY They have not developed any obvious circulatory impairment?

DR WHITE One case is still convalescing. The others have done well.

DR MALLORY From the anatomical point of view it is certainly the only logical form of treatment.

DR WYMAN RICHARDSON From the point of view of convention one wants to think several times before putting an old person to bed with out good reason. Apparently the critical period is three or four weeks. If a person is in bed for that long he is likely to stay there forever without complications.

## THE HAZARDS OF PUBLICITY

THE concerted effort to reduce the pneumonia death rate more rapidly than it is reducing itself has been worthy and proper. Health authorities, eminent physicians and committees representing all sorts of interested groups are contributing to the widespread trend and desire to make what we know about this disease available to as large a part of the population as possible. Much of this effort is necessarily in the direction of popular education. Syndicated medical columns, special articles and letters in the newspapers and periodicals, broadcasts under various auspices, insurance company and commercial advertising programs, all have tried to bring a hopeful message to the people. Even if a tube of tooth paste, a cough mixture or a little eye wash has been inadvertently disposed of on the side, there has

been disseminated a tremendous amount of more or less reliable information concerning our most prevalent infectious disease.

Unfortunately we have no technic by which we can simplify the truth and at the same time make it popular. To explain that there are "thirty-two kinds of pneumonia" hardly enlightens the public, nor does it state the facts. When we are cautious and precise, what we say becomes uninteresting as newspaper copy. If, on the other hand, we can devise catchwords and headlines that will attract the attention of the people we can have the publicity resources of the nation practically placed at our disposal. But acceptable headlines must be dramatic, and deliberate dramatization crushes the reality from any subject. The tendency to isolate a single passage or phrase from its context is also difficult to control, it is thus that slogans are made, and thus may be explained the fact that most of them are essentially without meaning. Such are the difficulties that beset the paths of those who would "educate" the public in the field of medicine.

Probably the most effective thrusts, for better or for worse, come about quite by accident. One such caught the editorial eyes of the country last month when a doctor said that people "just don't die" of pneumonia any more. The expression was a natural, using this noun in the American sporting sense. It was immediately hailed and used to preface the announcement of another substance claimed to have therapeutic value in pneumonia. Professional publicists could hardly have devised is apt a thought as this. It conveyed in a few easy words what pneumonia committees have conveyed only with difficulty in ponderous pages of written and spoken propaganda. It implied greater resource, greater skill and greater effort on the part of the doctor of today. It was professorial.

Effective as this pronouncement proved to be, it still needs one minor qualification. It is not true. It cannot alter the fact that people *do* die of pneumonia, and under the best medical and nursing supervision too.

Recently a new drug, variously known as sulfa-pyridine, pyridine sulfanilamide and M & B 693

## MASSACHUSETTS MEDICAL SOCIETY

## SHATTUCK LECTURE

Dr Wilder Penfield, director of the Montreal Neurological Institute and professor of neurology and neurosurgery at McGill University Faculty of Medicine, Montreal, will deliver the Shattuck Lecture at the one hundred and fifty-eighth annual meeting of the Massachusetts Medical Society, to be held in Worcester on June 6, 7 and 8. His title is "Epilepsy and the Cerebral Lesions of Birth and Infancy."

## POSTPARTUM HEMORRHAGE

Mrs. D., a nineteen-year-old primipara, was first seen on August 17, 1938, when she was about twenty-seven weeks pregnant.

Her family history was essentially negative except for a maternal aunt who died of pulmonary tuberculosis. The patient had had the usual childhood diseases, otherwise her past history was negative. Catamenia began at thirteen, were regular with a twenty-eight-day cycle and lasted four days without pain. Her last period was February 1, 1938, making her due for delivery November 8.

Examination at the time she was first seen disclosed a well-developed and nourished young woman. Her heart was not enlarged, there were no murmurs. The lungs were clear and resonant, there were no rales. The fundus lay midway between the umbilicus and the xiphoid cartilage. The vertex was presenting and floating. The fetal heart was heard best in the right lower quadrant, the rate being 135 per minute. Urinalysis was negative except for a slight trace of albumin. The Wassermann test and urethral and cervical smears were negative.

The patient's prenatal course was normal in all respects. There was no elevation of blood pressure above 120 systolic, 85 diastolic, at any time, no edema developed, nor any other untoward symptoms. Urinalysis was normal throughout the prenatal period.

Slight uterine contractions began at 9 a. m. on November 9, and the patient was delivered of a male child weighing 7 pounds, 14 ounces, by low midforceps at 4:45 p. m. on November 10, after a labor of approximately sixteen hours and after

full dilatation of slightly over three hours. A right lateral episiotomy was performed and was repaired with No. 2 chromic catgut while waiting for the placenta to separate. Fifteen minutes after the delivery of the baby a sudden profuse flow of blood occurred, apparently indicating partial separation of the placenta. The exact amount of blood was not determined, but it was estimated to be about 1000 cc. The patient went rapidly into shock, with sudden pallor, clammy skin, a weak, rapid, thready pulse and sighing respirations. Two cubic centimeters of posterior pituitary extract was immediately administered and the placenta was expressed intact by the Credé method. Two cubic centimeters of ergot was administered following the delivery of the placenta, and the fundus was gently massaged. The patient's pulse rate was 170 per minute, and her general condition was very poor. She was placed in Trendelenburg position, and 500 cc. of 5 per cent glucose in saline solution was given intravenously, and 1/6 gr. of morphine subcutaneously. When the patient was returned to bed, a clysis consisting of 1000 cc. of 5 per cent glucose in saline solution was administered. The patient's condition gradually improved, and four hours post partum her pulse had a rate of 120 per minute and was of fairly good quality. The fundus remained well contracted, and the flow was normal.

Following the initial setback the patient improved rapidly. She was given Feosol and liver extract daily and was discharged on the fourteenth day post partum, with a hemoglobin of 60 per cent and red-cell count of 3,500,000.

*Comment.* This case illustrates a type of postpartum hemorrhage that is frequently seen. The placenta separates quickly after the birth of the baby and is accompanied by a tremendous amount of bleeding. Fortunately oxytocics will usually control the uterus. Had this uterus not contracted well, packing might have been considered, transfusion would probably have been necessary and hysterectomy might have had to be performed. Conservative treatment is all that is necessary in many of these cases, but this case illustrates once more the need that may arise at any time for transfusion and the advisability of being prepared for such an emergency.

## LEGISLATIVE NOTES

## THE CHIROPRACTORS WIN THE FIRST ROUND

Last year the Legislature set up a recess commission to study the matter, among others, of licensing chiropractors. The commission consisted of Senator Jarvis Hunt, of North Attleboro,

A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are welcomed and will be discussed by members of the section.

has been distributed for general use. Many feel that this release was premature. The drug has already received a great deal of notice as a therapeutic agent in pneumococcal pneumonia. The practicing physician is now faced with the decision whether to use serum or this new drug.

Bullowa, Plummer and Finland\* have made a strong plea for caution and conservatism in accepting this new agent because of our lack of knowledge of its dangers and of the limitations of its usefulness. In view of the unprecedented publicity in the lay press accorded to the drug we are entirely in agreement with this plea. They recommend that the drug be given a thorough trial in parallel with specific serum before it is enthusiastically endorsed to the exclusion of the latter. Only a large group of observations will throw light on this problem, and it is necessary that every case possible be typed if this information is to be obtained and be of value.

Of course the incidence and mortality of the disease are decreasing, but every doctor who actually cares for pneumonia patients knows that they still die all too frequently. This should be understood by all, especially by those who have lost members of their families by pneumonia during the current year. The millennium as it concerns this disease is far, far away!

### THE EXPLORER PHYSICIAN

ONE of the greatest African travelers, who pioneered in opening up vast territories for Great Britain under the sponsorship of the African Association in the late eighteenth century, was a physician, Mungo Park. Born under humble circumstances, the seventh of thirteen children, he was apprenticed to a surgeon in Selkirk, Scotland, and received his medical degree at Edinburgh at the age of twenty. Coming to London, as most good Scots did, he fortunately fell under the eye of Sir Joseph Banks, then president of the Royal Society. Through Banks, who helped so many young men, Park obtained a post as assistant medical officer on an East Indian boat and spent some time in Su-

matra. Bringing home rare plants to Banks, he was not forgotten by this leader of scientific thought in London. Two years later Banks recommended him to the African Association, and so this young man of twenty-four headed an exploration party to determine the source of the Niger River.

He was absent from England from May, 1795, until December, 1797, and the account of his travels, written in 1798, was published in 1799. The book, so modestly and simply written, became popular at once and required three editions in the same year. Handsome, six-foot Park, a little reserved in manner, became famous overnight, and one can easily imagine what receptions he must have had in London under the guidance of Banks and the members of the Royal Society.

Park, however, retired quietly to Scotland and married the daughter of his old preceptor in Selkirk, an action in every way characteristic of the man. After a few years of practice at Peebles, where he formed a warm friendship with Walter Scott, Park set out on a second expedition to the Niger. All the party were wiped out by fever or accident and Park, one of the last survivors, died in 1806. His body and records were never found.

His *Travels in the Interior Districts of Africa* (London, 1799), relating the story of his hardships during the first exploration, is a splendid narrative, written in an easy style and as fine an adventure book as one could wish for. Much of the trip was made on foot, with only a servant, he was robbed, taken prisoner, escaped, suffered from severe fever, and at last, utterly exhausted, was forced to turn back for lack of funds to purchase food. He had, however, covered three thousand miles under the most trying circumstances.

Park's high-mindedness and perseverance are now legend. His letter to Lord Camden, when he was setting out on his second and what proved to be his last effort, is often quoted: "My dear friends, Mr. Anderson and likewise Mr. Scott, are both dead, but though all Europeans who are with me should die, and though I were myself half dead, I would still persevere, and if I could not succeed in the object of my journey, I would at least die on the Niger."

\*Bullowa, J. G. M., Plummer, N., and Finland, M. Sulfapyridine in the treatment of pneumonia. J. A. M. A. 112:570, 1939.

requires that supplementary reports be sent to this department.

It has been passed to be engrossed.

*H 74* Bill requiring the clerk or registrar in each city or town to give to persons who file notice of intention of marriage suitable information concerning gonorrhea and syphilis. The bill was proposed by the Department of Public Health and it contains no compulsion.

This bill was heard by the Committee on Public Health on March 28

*H 75* Bill making various changes in the laws relating to foods and drugs. The bill was proposed by the Department of Public Health in order to bring the state law into line with the new federal act.

It will be heard by the Committee on Public Health on April 13

*H 670* Bill providing for the issuance of certificates of approval of bacteriological laboratories by the Department of Public Health. The bill was proposed by the Massachusetts Central Health Council and is similar to the one favored by the Massachusetts Medical Society last year

It was heard by the Committee on Public Health on March 23. There was no opposition.

*H 852* Bill requiring licensing of hospitals, convalescent homes and nursing homes. This bill was proposed by the Massachusetts Central Health Council and provides for the Department of Public Health to set up certain standards of health and enforce them

It was heard a second time by the Committee on Public Health on March 23

*H 1407* Bill prohibiting aliens from practicing medicine. This bill was proposed by Rep. Vaughan and is poorly written. It provides that no license be granted to an alien until his first papers have been filed but allows certain very broad exceptions.

This bill was heard by the Committee on Public Health on March 14. An amended bill has been presented.

#### OPPOSE

*H 287* Bill providing for a marriage protection law by requiring a physician's examination and certificate before issuance of marriage licenses. This bill was proposed by Rep. Cutler and it needs major revision before being satisfactory

It was heard before the Committee on Public Health on March 28. (The revised bill, printed above, was favored by the Society)

*H 551* Bill requiring that notices of intention of marriage shall be accompanied by a physician's certificate that neither party is infected with syphilis. This bill was proposed by Dr. William Frankman and also needs major revision before being satisfactory

It was heard by the Committee on Public Health on March 28

*H 758* Bill providing authority to the Board of Registration of Nurses to limit further training of nurses of all classes and attendants under certain conditions. The bill was proposed by Miss Josephine E. Thurlow but is against public policy

It was heard by the Committee on Public Health on February 2 and again on March 7

*H 759* Bill providing for training and licensing of first class bedside nurses. This bill was proposed by Miss Josephine E. Thurlow, but is against public policy

It was heard by the Committee on Public Health on February 2 and again on March 7

*H 858* Bill regulating the practice of nursing. This bill was proposed by the Massachusetts State Nurses Association, and while it is better than last year's bill, some of last year's defects are still present.

It was heard by the Committee on Public Health on February 2 and again on March 7

*H 985* Bill requiring doctors of medicine and doctors of osteopathy on the Board of Registration in Medicine. This bill was proposed by the Massachusetts Osteopathic Association and would put two osteopathic physicians on the Board

It was heard before the Committee on Public Health on February 9. Our ballots were presented to the committee. The committee has voted leave to withdraw, and this report has been accepted in the House.

*H 986* Bill providing for a doctor of medicine and a doctor of osteopathy on the Approving Authority and the status of approvals by the American Medical Association and the American Osteopathic Association. This bill was proposed by the Massachusetts Osteopathic Association, it weakens the Approving Authority

This bill was heard February 9 by the Committee on Public Health. Our ballots were presented to the committee. The committee has voted leave to withdraw, and this report has been accepted in the House.

*H 1401* Bill providing that certificates of vaccination or non-vaccination shall no longer be required as a prerequisite to the attendance of any child in public schools. This is a typical anti-vaccination bill

It will be heard before the Committee on Public Health on April 4

*H 1898* Bill providing for the establishment and administration of a system of health insurance. This bill was proposed by the State Industrial Council of the Congress of Industrial Organization (CIO) and means complete state insurance medicine with a 4½ per cent pay roll tax. It represents real regimentation of physicians

It was heard by the Committee on State Administration on March 15. There is to be a second hearing on March 31

CHARLES C. LUND, *Chairman*

Committee on State and  
National Legislation

#### TREASURER'S REPORT COVERING REFUND DISTRIBUTION

The Treasurer of the Massachusetts Medical Society makes the following report regarding the refund to district societies for 1939

The Council voted to distribute the sum of \$4000 to district societies. The total number of payments of annual dues received by the Treasurer by March 2, to be counted for the refund, was 3916. Therefore the refund to the district societies for each paid fellow is \$1.021

The following table gives the number of payments in, and the refund to each district as of March 23

chairman, Representatives A M Bessette, of New Bedford, Oscar DeRoy, of Holyoke, and Charles Savage, of West Roxbury, and the following three men appointed by Governor Hurley Edward W Toomey, of Cambridge, Timothy W Cronin, of Cambridge, and Frederick J Hogan, of Winthrop Hearings concerning chiropractic legislation were held in Boston, Springfield, New Bedford and Lowell At these hearings the district legislative committees and many members of the profession tried to explain in a dignified way the importance of a single standard of education for the practice of healing Immediately after the Legislature convened on January 4 the Attorney-General advised that members of such commissions that failed of election could no longer serve on them As the report of the commission had not been written, due to the late commencement of the Legislature and to delay on the part of Governor Hurley in making his appointments, a new man had to be appointed to replace Mr Savage who was not re-elected Representative M J Capeles, of Pittsfield, was appointed Mr Capeles, who attended none of the hearings, has joined Messrs Bessette, DeRoy and Cronin in signing a majority report in favor of the chiropractors Messrs Capeles and Bessette voted for the chiropractors in 1936, so that they are not new converts to the cause

The loss of the first round in this legislative struggle is not fatal, but it means that we must go to work and work hard The chiropractors are already flooding the legislators with letters and petitions The bill must be stopped! We cannot do so by any half measures Each member of the Society resident in Massachusetts should inspire at least ten letters from friends or patients to their representatives and senators opposing this legislation As soon as the date is set for the hearing every doctor in the State should put the date on his calendar and plan either to come himself or to send a voter as a representative The date will be put in this column as soon as it is known

These procedures of course are extreme, and we should not have to use them However, there are a number of legislators who are very much impressed by such interest on the part of voters and who will vote according to their estimate of their constituents' desire Remember—it is your *duty* to be present or to be represented at the Gardner Auditorium at the State House on the day set at 10 00 a m

#### PRE-MARITAL SYPHILIS BILLS

As reported to the Council on February 1 and in this column in some prior issues none of the

bills for pre-marital examination for syphilis have been approved by the Committee on State and National Legislation A practically new bill, which is deemed to be suitable, has been drawn up and agreed to by most of the parties interested in the subject The hearing at the State House will have been held before this issue of the *Journal* is out The committee will have put the Society on record in favor of this bill The text follows

#### HOUSE BILL 287 (revised)

AN ACT PROVIDING FOR A MARRIAGE PROTECTION LAW, BY  
REQUIRING PHYSICIAN'S EXAMINATION AND CERTIFICATE  
BEFORE ISSUANCE OF MARRIAGE LICENSES

*Section 20 of Chapter 207 of the General Laws of Massachusetts is hereby amended*

Such intention of marriage shall not be accepted by the clerk or registrar until he has received from each applicant a statement signed by a registered physician, stating that said physician has examined the applicant and, if he has discovered evidence of any infectious disease which has been declared to be dangerous to the public health by the Department of Public Health, that he has informed both applicants of the nature of the disease and of the possibilities of transmitting it to his or her marital partner or to their children Such examination by said physician shall include a standard serological test for syphilis and said test shall be made by a laboratory of the State Department of Public Health or by a laboratory approved for this test by the Department

The physician's examination and the laboratory test shall be made not more than thirty days before the issuance of the marriage license A marriage license issued in accordance with this act shall be valid for thirty days, after which time it shall become invalid

Any person who shall fail to comply with the provisions of this act shall be subject to a penalty of not less than ten dollars (\$10 00) nor more than one hundred dollars (\$100 00)

\* \* \*

#### MISCELLANEOUS BILLS

Below is listed the progress in the Legislature of some of the bills in which the Massachusetts Medical Society is interested

#### FAVOR

S 258 See issue of March 9 No change in status

H 59 Identical with S 258

H 60 Bill requiring annual licensing of qualified physicians

It was heard by the Committee on Public Health on February 9 and they have been given the ballots recently filled out by members of the Society, but no report has yet been made

H 72 Bill providing for the care of certain infants prematurely born. It was proposed by the Department of Public Health, and corrects defects in the previous bill.

This bill was amended to H 2080 and has been passed to be engrossed

H 73 Bill providing for supplementary reporting of congenital deformities and birth injuries in infants. The bill was proposed by the Department of Public Health and

requires that supplementary reports be sent to this department.

It has been passed to be engrossed

*H 74* Bill requiring the clerk or registrar in each city or town to give to persons who file notice of intention of marriage suitable information concerning gonorrhea and syphilis. The bill was proposed by the Department of Public Health and it contains no compulsion

This bill was heard by the Committee on Public Health on March 28

*H 75* Bill making various changes in the laws relating to foods and drugs. The bill was proposed by the Department of Public Health in order to bring the state law into line with the new federal act.

It will be heard by the Committee on Public Health on April 13

*H 670* Bill providing for the issuance of certificates of approval of bacteriological laboratories by the Department of Public Health. The bill was proposed by the Massachusetts Public Health Association and is similar to the one favored by the Massachusetts Medical Society last year

It was heard by the Committee on Public Health on March 23. There was no opposition

*H 852* Bill requiring licensing of hospitals, convalescent homes and nursing homes. This bill was proposed by the Massachusetts Central Health Council and provides for the Department of Public Health to set up certain standards of health and enforce them

It was heard a second time by the Committee on Public Health on March 23

*H 1407* Bill prohibiting aliens from practicing medicine. This bill was proposed by Rep. Vaughan and is poorly written. It provides that no license be granted to an alien until his first papers have been filed but allows certain very broad exceptions

This bill was heard by the Committee on Public Health on March 14. An amended bill has been presented

#### OPPOSE

*H 287* Bill providing for a marriage protection law by requiring a physician's examination and certificate before issuance of marriage licenses. This bill was proposed by Rep. Cutler and it needs major revision before being satisfactory

It was heard before the Committee on Public Health on March 28. (The revised bill, printed above, was favored by the Society.)

*H 551* Bill requiring that notices of intention of marriage shall be accompanied by a physician's certificate that neither party is infected with syphilis. This bill was proposed by Dr. William Frankman and also needs major revision before being satisfactory

It was heard by the Committee on Public Health on March 28

*H 758* Bill providing authority to the Board of Registration of Nurses to limit further training of nurses of all classes and attendants under certain conditions. The bill was proposed by Miss Josephine E. Thurlow but is against public policy

It was heard by the Committee on Public Health on February 2 and again on March 7

*H 759* Bill providing for training and licensing of first class bedside nurses. This bill was proposed by Miss Josephine E. Thurlow, but is against public policy

It was heard by the Committee on Public Health on February 2 and again on March 7

*H 858* Bill regulating the practice of nursing. This bill was proposed by the Massachusetts State Nurses Association, and while it is better than last year's bill, some of last year's defects are still present.

It was heard by the Committee on Public Health on February 2 and again on March 7

*H 985* Bill requiring doctors of medicine and doctors of osteopathy on the Board of Registration in Medicine. This bill was proposed by the Massachusetts Osteopathic Association and would put two osteopathic physicians on the Board

It was heard before the Committee on Public Health on February 9. Our ballots were presented to the committee. The committee has voted leave to withdraw, and this report has been accepted in the House.

*H 986* Bill providing for a doctor of medicine and a doctor of osteopathy on the Approving Authority and the status of approvals by the American Medical Association and the American Osteopathic Association. This bill was proposed by the Massachusetts Osteopathic Association, it weakens the Approving Authority

This bill was heard February 9 by the Committee on Public Health. Our ballots were presented to the committee. The committee has voted leave to withdraw, and this report has been accepted in the House.

*H 1401* Bill providing that certificates of vaccination or non-vaccination shall no longer be required as a prerequisite to the attendance of any child in public schools. This is a typical anti-vaccination bill.

It will be heard before the Committee on Public Health on April 4

*H 1898* Bill providing for the establishment and administration of a system of health insurance. This bill was proposed by the State Industrial Council of the Congress of Industrial Organization (C.I.O.) and means complete state insurance medicine with a 4½ per cent pay roll tax. It represents real regimentation of physicians.

It was heard by the Committee on State Administration on March 15. There is to be a second hearing on March 31

CHARLES C. LUND, *Chairman*  
Committee on State and  
National Legislation

## TREASURER'S REPORT COVERING REFUND DISTRIBUTION

The Treasurer of the Massachusetts Medical Society makes the following report regarding the refund to district societies for 1939

The Council voted to distribute the sum of \$4000 to district societies. The total number of payments of annual dues received by the Treasurer by March 2, to be counted for the refund, was 3916. Therefore the refund to the district societies for each paid fellow is \$1021

The following table gives the number of payments in, and the refund to, each district as of March 23

DISTRICT	NUMBER	
	REPORTED	REFUND PAID
Barnstable	42	\$43 07
Berkshire	105	107.30
Bristol North	50	51 22
Bristol South	155	158.33
Essex North	175	178 75
Essex South	206	210 39
Franklin	39	40 00
Hampden	236	241 02
Hampshire	57	58.37
Middlesex East	109	111.39
Middlesex North	105	107 30
Middlesex South	786	802 57
Norfolk	664	678 00
Norfolk South	113	115 44
Plymouth	117	119 53
Suffolk	527	538 13
Worcester	348	355 37
Worcester North	82	83 82
	3916	\$4000 00

In 1938, for comparison, the total number of payments for the refund was 3784

CHARLES S BUTLER, M.D., *Treasurer*

#### MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning April 3

##### BARNSTABLE

Sunday, April 9, at 4 00 p m., at the Cape Cod Hospital, Hyannis Subject—The Indications and Contraindications for Removal of Tonsils and Adenoids Instructor Warren R. Sisson Donald E. Higgins, *Chairman*

##### BERKSHIRE

Thursday, April 6, at 4 30 p m., at the House of Mercy Hospital, Pittsfield Subject—Gonorrhea Modern treatment of gonorrhea. Instructor Oscar F. Cox, Jr. Melvin H. Walker, *Chairman*

##### FRANKLIN

Wednesday, April 5, at 8 00 p m., at the Franklin County Public Hospital, Greenfield. Subject—Sepsis Instructor A. Gordon Gauld. Halbert G. Stetson, *Chairman*

##### HAMPDEN

Thursday, April 6, at 4 00 p m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8 00 p m., in the Outpatient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. Subject—Bright's Disease and Hypertension Evaluation of new therapy, diagnosis Instructor W. Richard Ohler George L. Schadt, *Chairman*

##### MIDDLESEX SOUTH

Tuesday, April 4, at 4 30 p m., at the Cambridge Hospital, 330 Mt. Auburn Street, Cambridge. Sub-

ject—Whooping Cough The present status of vaccine therapy both as prophylactic and therapeutic measure, the early diagnosis by laboratory procedures, and the treatment of complications. Instructor Louis K. Diamond. Alexander A. Levi, *Chairman*

##### SUFFOLK

Thursday, April 6, at 4 30 p m., in John Ware Hall, Boston Medical Library, 8 Fenway, Boston Subject—Latent syphilis diagnosis and treatment. Instructor C. Guy Lane. Reginald Fitz, *Chairman*

#### DEATHS

BENNER—RICHARD S. BENNER, M.D., of Springfield, died March 23. He was in his sixty-fourth year.

Dr. Benner received his degree from the Harvard Medical School in 1903. He was a staff member at the Springfield and Wesson hospitals, Springfield. Among his affiliations were fellowships in the Massachusetts Medical Society and the American Medical Association and memberships in the New England Obstetrical and Gynecological Society, the American College of Surgeons and the New England Surgical Society.

His widow, two sons and two daughters survive him.

BYRNE—CLAUDIUS J. BYRNE, M.D., of 1066 Main Street, Worcester, died March 18. He was in his fifty-sixth year.

Born in Moultonboro, New Hampshire, he attended high school in Manchester, New Hampshire, and was graduated from Tilton Seminary, Tilton, New Hampshire. He received his degree from Tufts College Medical School in 1910.

Dr. Byrne was one of the two senior surgeons at the Worcester City Hospital and last January was elected president of the Worcester City Hospital Staff Association. He was also surgeon at Wickwire Spencer Steel Company. His memberships included the Massachusetts Medical Society, the American Medical Association and the American College of Surgeons.

His widow, a son and a sister survive him.

DRURY—JOHN N. DRURY, M.D., of 9 Central Street, Lowell, died November 19, 1938. He was in his fifty-eighth year.

Born in Lowell, he attended the local schools and received his degree from New York University College of Medicine in 1904. He also graduated from the Bellevue Medical School. Dr. Drury was a staff member of the Bellevue Hospital for eight years and later conducted a private practice in New York City until 1914, when he returned to Lowell.

A great deal of his time was given to the tuberculosis clinic conducted by the city health department. Dr. Drury was a fellow of the Massachusetts Medical Society and of the American Medical Association.

His widow, a daughter, a son, his father, three brothers and several nieces and nephews survive him.

GRAY—ELIZABETH T. GRAY, M.D., of 149 Warren Street, Roxbury, died March 24. She was in her seventy-seventh year.

Born in Roxbury, she attended Girls High School and was graduated from the Posse School of Physical Education in 1892. She received her degree from the Woman's Medical College of the New York Infirmary for Women and Children in 1895.

After her retirement ten years ago she was appointed consulting surgeon of the New England Hospital for Women and Children and at the time of her death was a director and faculty member of the Posse School

A nephew survives her

**McLAUGHLIN**—**JOSEPH I McLAUGHLIN, M.D.**, of 92 Walnut Avenue, Roxbury, died March 26. He was in his seventy ninth year

Born in Boston he was educated in the Boston schools and at Boston College and received his degree from the Harvard Medical School in 1890. Dr McLaughlin was appointed physician at the Charlestown State Prison in 1891 and had continued his private practice in Roxbury until several months ago

He was a fellow of the Massachusetts Medical Society and the American Medical Association

Two sisters survive him.

**WOODALL**—**CHARLES S WOODALL, M.D.**, of Brandon, Vermont, died March 26. He was in his forty seventh year

He received his degree from the Harvard Medical School in 1924. For twelve years he served as assistant superintendent of the Fernald State School in Waverley and resigned to become the head of the Brandon State School. He was a diplomate of the American Board of Neurology and Psychiatry and a member of the National Board of Medical Examiners

Dr Woodall was a fellow of the Massachusetts Medical Society and the American Medical Association and held memberships in the American Psychiatric Association and the New England Society of Psychiatry

His widow survives him

## MISCELLANY

### YOUR HEALTH BROADCASTS

The next series of 'Your Health' broadcasts, sponsored by the American Medical Association and the National Broadcasting Company and heard over the Blue Network each Wednesday at 2 00 p m., is entitled 'Health Education'. It consists of four broadcasts as follows

April 5 Don't Believe Everything!

Fallacies and popular beliefs that are not true and that influence behavior in a manner detrimental to health

April 12 Learning to Live.

Elements of mental hygiene, getting along with people, adjustment to environment.

April 19 Accidents Don't Just Happen—

Accidents in the home and on the highway and ways to avoid them.

April 26. What Is a Doctor?

The characteristics of a reputable physician as distinguished from cultists, quacks, fakers, faddists or exploiters.

### MANIFESTO BY BALKAN MEDICAL UNION

The Balkan Medical Union, in session at Istanbul, for the fifth Medical Week,

HAVING TAKEN INTO CONSIDERATION the terrible sufferings which a total war will bring upon the civil population of open towns with a total lack of any adequate means of protection, and

HAVING DISCOVERED that even in its restricted form the project of 'sanitary towns' has not yet been adopted, and that all efforts made to protect civilians against chemical warfare have till now remained as proposals only, and that even the protocol prohibiting the use of asphyxiating gas has not yet been ratified by all nations, therefore

HAS DECIDED to address itself to doctors of every nation with an appeal to take active measures and to fulfill this professional and humanitarian duty of awakening and stirring public opinion

The Balkan Medical Union believes that only enlightened international opinion can make plain the imminence of the danger and the proved uselessness, even for the victor, of these terrible atrocities, and can thus lead to effective action. The immutable truth that *hate breeds only hate and atrocity breeds vengeance*, must be impressed on everyone.

Prof Dr Bensis, Dr Scaramanga (Athènes), Dr Zika Marković, Prof Dr K. Sahović, Dr M. Simović (Beograd), Prof Dr Gheorghiu, Dr Popescu Buzzeu (Bucarest), Prof Dr Akil Muhtar Ozden, Prof Sedat Tavat, Prof. Dr A Süheyl Ünver (Istanbul)

## CORRESPONDENCE

### UNITED JEWISH CAMPAIGN

*To the Editor* At this time of extreme need for the Jews, the question is raised, "What are Jews of America doing to help?" It has come to my attention that a nationwide campaign is being launched by this race to raise a tremendous sum of money to help in giving relief.

On March 19, the United Jewish Campaign officially opened with the object of raising money for the purposes listed below

1 For the relief of the dislocated groups in Europe, under the direction of the Joint Distribution Committee.

2 For the United Palestine Appeal, the funds of which are to be used in co-ordinating settlement and protecting in every way both the settled population and the refugees who have flocked to Palestine to the number of 200,000 in the past few years

3 For the National Co-ordinating Committee Fund, which has the purpose of maintaining and distributing refugees in the United States and elsewhere.

In addition, certain re-educational and cultural programs are being financed. The scope of the relief work to be done is world wide, and the suffering to be relieved is abysmal

Naturally, the Jews will take care of the larger part of the financing of this immense problem. However, I believe that there are many doctors in this community who may wish to show their sympathy and good will by making a small contribution toward this campaign which is humane in the most complete meaning of the word and which is to uphold the dignity and defend the liberty of human beings

Those who are interested to do so may send a note or a check to Dr Abraham Myerson, Lister Building, Boston, who is chairman of the Medical Committee.

HILBERT F DAY, M D

412 Beacon Street,  
Boston.

# ARTICLES ACCEPTED BY THE AMERICAN MEDICAL ASSOCIATION COUNCIL ON PHARMACY AND CHEMISTRY

*To the Editor* In addition to the articles enumerated in our letter of February 7 the following have been accepted

## Abbott Laboratories

Abbott's Nicotinic Acid Tablets 50 mg  
Abbott's Nicotinic Acid Tablets 100 mg

## Arzol Chemical Co

Mercurochrome Applicators — Arzol

## Eli Lilly & Co

Ampules Metycaine 2 per cent, 30 cc, in rubber-stoppered vials

## Mead Johnson & Co

Mead's Nicotinic Acid Tablets, 20 mg

## Medical Arts Laboratory

Rabies Vaccine (Killed Virus) packages of 7 vials

## Merck & Co., Inc.

Nicotinic Acid — Merck

## Wm S Merrell Co

Ephedrine Sulfate — Merrell  
Ampule Solution Ephedrine Sulfate — Merrell,  $\frac{3}{4}$  gr (0.05 gm), 1 cc.  
Ampule Solution Mercury Succinimide — Merrell,  $\frac{1}{6}$  gr (0.01 gm.), 1 cc

## The National Drug Co

Immune Globulin (Human)

## The Upjohn Co

Solution Procaine Hydrochloride 2 per cent, 30 cc vials  
Solution Procaine Hydrochloride  $\frac{1}{2}$  per cent with Epinephrine, 5 cc.  
Ampule Solution Procaine Hydrochloride 2 per cent with Epinephrine, 1 cc.  
Ampule Solution Procaine Hydrochloride 2 per cent with Epinephrine, 3 cc.  
Solution Procaine Hydrochloride 1 per cent with Epinephrine, 30 cc. vials  
Solution Procaine Hydrochloride 2 per cent with Epinephrine, 30 cc. vials

Chicago, Illinois

## NOTICES

### REMOVAL

BERNARD ZUCKERMAN, M.D., announces the removal of his office to 1804 North Avenue, Bridgeport, Connecticut.

### ANNOUNCEMENT

DR. WILLIAM E. BROWNE, of 587 Beacon Street, Boston, has resumed in full his former duties of practice following an illness of several months.

## UNITED STATES CIVIL SERVICE EXAMINATIONS

Associate Medical Officer, \$3200 a Year

Applications must be on file with the United States Civil Service Commission at Washington, District of Columbia, not later than April 10

Applicants must have had at least one year of general internship, or one year in a special branch. They must have been graduated from a medical school of recognized (Class A) standing with the degree of M.D., subsequent to May 1, 1934

Associate Health Education Specialist, \$3200 a Year  
Assistant Health Education Specialist, \$2600 a Year

Applications must be on file with the United States Civil Service Commission at Washington, District of Columbia, not later than April 17

Applicants for either position must have successfully completed a full four-year course leading to a bachelors degree in a college or university of recognized standing

Applicants for the position of assistant health education specialist must show at least two years of postgraduate study successfully completed toward a certificate, diploma or a degree in hygiene or public health in a college or university of recognized standing

\* \* \*

The necessary forms may be obtained from the Secretary, Board of the United States Civil Service Examiners, at any first-class post office, from the United States Civil Service Commission, Washington, District of Columbia, or from the United States Civil Service district office.

## BOSTON DOCTORS' SYMPHONY ORCHESTRA

*Nicolas Slonimsky*

Rehearsals of the newly organized Boston Doctors' Symphony Orchestra, conducted by Nicolas Slonimsky, are held every Thursday evening at 7 30 at Hampton Court Hotel, 1223 Beacon Street, Brookline.

Membership is still open. All physicians, dentists and medical and dental students who are interested should communicate with Dr Julius Loman, Pelham Hall Hotel, Brookline (BEA 2430)

## MEDICAL CLINIC AT THE PETER BENT BRIGHAM HOSPITAL

At 3 30 p.m. on Thursday, April 6, in the amphitheater of the Peter Bent Brigham Hospital, Dr William P Murphy will give a medical clinic. Practitioners and medical students are cordially invited to attend

## HOSPITAL COUNCIL

The annual meeting and luncheon of the Hospital Council of Boston will be held at the Palmer Memorial, New England Deaconess Hospital, 195 Pilgrim Road, Boston, on Tuesday, April 11, at 12 30 o'clock.

Miss Carrie M. Hall, R.N., will report on her investigation of nursing homes.

## NEW YORK ACADEMY OF MEDICINE

The Twelfth Graduate Fortnight of the New York Academy of Medicine will be held from October 23 to November 3. The subject of the Fortnight will be "The Endocrine Glands and Their Disorders."

The program will include clinics and clinical demonstrations at many of the hospitals of New York City, evening addresses and appropriate exhibits. The evening sessions at the Academy will be addressed by recognized authorities in their special fields.

A complete program and registration blank may be secured by addressing Dr. Mahlon Ashford, New York Academy of Medicine, 2 East 103rd Street, New York City.

## DELTA OMEGA LECTURE

The eleventh Delta Omega Lecture of the Department of Biology and Public Health of Massachusetts Institute of Technology will be held at the Massachusetts Institute of Technology, Cambridge, on Friday, March 31, at 5:00 p.m.

Dr. John E. Gordon will speak on "Public Health in the Balkans."

The lecture is open to all who are interested.

## AMERICAN ASSOCIATION OF INDUSTRIAL PHYSICIANS AND SURGEONS

The twenty-fourth annual meeting of the American Association of Industrial Physicians and Surgeons with the American Conference on Occupational Diseases and Industrial Hygiene will be held at the Hotel Statler, Cleveland, Ohio, June 5, 6, 7 and 8. A program of timely interest and importance will be presented by speakers of outstanding experience in all the medical and engineering problems involved in industrial health. A cordial invitation is extended to all whose interests bring them in contact with these problems. Information regarding hotel accommodations, and so forth, may be obtained from A. G. Park, Convention Manager, 540 North Michigan Avenue, Chicago.

## JOSEPH H. PRATT DIAGNOSTIC HOSPITAL

Bennet Street, Boston  
Auditorium, 9-10 a.m.

## MEDICAL CONFERENCE PROGRAM

Tuesday, April 4—Low Back Pain. Dr. J. D. Adams  
Wednesday, April 5—Hospital Case Presentation. Dr. S. J. Thannhauser  
Thursday, April 6—The Status of Tuberculosis in the British Isles. Dr. S. V. Pearson  
Friday, April 7—Adrenal Function and Angina Pectoris (Theory and Therapy). Dr. William Raab  
Saturday, April 8—Hospital Case Presentation. Dr. S. J. Thannhauser  
Tuesday, April 11—Physical Examinations of Groups. Dr. R. W. Buck.  
Wednesday, April 12—Hospital Case Presentation. Dr. S. J. Thannhauser  
Thursday, April 13—Metrazol Therapy in Dementia Praecox. Dr. Arthur Berk.  
Friday, April 14—Here and There in Endocrinology. Dr. Fuller Albright.  
Saturday, April 15—Hospital Case Presentation. Dr. S. J. Thannhauser  
Tuesday, April 18—Some Newer Aspects of the Treatment of Acidosis. Dr. Nelson R. Saphir  
Thursday, April 20—Medical Social Service Case Presentation. District Service and Social Service Staff

Friday, April 21—Ascorbic Acid. Dr. Allan Butler  
Saturday, April 22—Hospital Case Presentation. Dr. S. J. Thannhauser  
Tuesday, April 25—Diagnosis of Atypical Jaundice. Dr. William Dameshek.  
Wednesday, April 26—Hospital Case Presentation. Dr. S. J. Thannhauser  
Thursday, April 27—Alcohol. Chemical tests for alcoholism. Dr. Sydney Selesnick.  
Friday, April 28—Heredity and Environment in Relation to Intelligence, Personality and Mental Disease. Dr. Abraham Myerson.  
Saturday, April 29—Hospital Case Presentation. Dr. S. J. Thannhauser

FAULKNER HOSPITAL  
CLINICOPATHOLOGICAL CONFERENCE

The monthly clinicopathological conference of the Faulkner Hospital will be held on Thursday, April 6, at 5:00 p.m.

There will be a discussion of cases by Drs. J. S. Hodgson and G. M. Morrison.

## SOCIETY MEETINGS AND CONFERENCES

## CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING MONDAY, APRIL 3

## MONDAY APRIL 3

First Annual Regional Convention of the Association of Medical Students. Harvard Medical School

\*4 p.m. Physicians and medical students are cordially invited to attend a clinic presented by the medical, surgical and orthopedic services of the Infants and Children's hospitals in the amphitheater of the Children's Hospital.

## TUESDAY APRIL 4

9:10 a.m. Joseph H. Pratt Diagnostic Hospital. Low Back Pain. Dr. J. D. Adams.

10 a.m. 12:30 p.m. Tumor clinic. Boston Dispensary.

## WEDNESDAY APRIL 5

\*9:10 a.m. Joseph H. Pratt Diagnostic Hospital. Hospital case presentation. Dr. S. J. Thannhauser.

\*12 m. Clinicopathological conference. Children's Hospital amphitheater.

## THURSDAY APRIL 6

\*9:10 a.m. Joseph H. Pratt Diagnostic Hospital. The Status of Tuberculosis in the British Isles. Dr. S. V. Pearson.

\*3:30 p.m. Medical clinic at the Peter Bent Brigham Hospital.  
5 p.m. Faulkner Hospital clinicopathological conference.

## FRIDAY APRIL 7

9:10 a.m. Joseph H. Pratt Diagnostic Hospital. Adrenal Function and Angina Pectoris (Theory and Therapy). Dr. William Raab.

\*10 a.m. 12:30 p.m. Tumor clinic. Boston Dispensary.

12 m. Urological conference, Massachusetts General Hospital lower outpatient amphitheater.

## SATURDAY APRIL 8

\*9:10 a.m. Joseph H. Pratt Diagnostic Hospital. Hospital case presentation. Dr. S. J. Thannhauser.

10 a.m. 12 m. Staff rounds of the Peter Bent Brigham Hospital. Conducted by Dr. Henry A. Christian.

Open to the medical profession

## BOOK REVIEWS

*The Open Mind Elmer Ernest Southard, 1876-1920*  
Frederick P Gay 324 pp Chicago Normandie House, 1938 \$5.00

Why a biography of Elmer Ernest Southard? To his friends, associates and students, this question seems entirely unnecessary. The biographer, Dr Frederick P Gay, professor of bacteriology at Columbia University College of Physicians and Surgeons, certainly never had any doubt in his own mind that the life and work of Southard made him a proper subject for a biography. Not because Southard was the first Bullard Professor of Neuropathology at Harvard Medical School and the first director of the Boston Psychopathic Hospital, not merely because he was an outstanding chess player and the favored disciple of William James and Josiah Royce, but because, in the words of the biographer "Ernest Southard was a great deal more than an intellectual prodigy who scattered in spiration and, it must be confessed, at times dismay, among the orthodox. He was a great human being. He was a unique, directive and often a predominating influence in the lives of many men and women. He seldom left anyone, who passed more than a fleeting moment in his company, indifferent."

From Laun School days, Dr Gay believed that his friend was unique. He kept every letter from Southard, and he finally concluded that Southard was a 'genius'. In essence, the writing of the biography was a work of love and probably there was a compulsive drive toward its accomplishment. The biographer, being a scholar and scientist, a friend from boyhood days, a co-student and

colleague, and for a time a co-worker, and throughout Southard's life, a confidant, is eminently equipped not only to present the life and character of Southard, his views and his philosophy, but also to interpret his scientific accomplishments and to evaluate his work and his contribution to medicine and to society. This is what Dr Gay has tried to accomplish.

The book is divided into seventeen chapters dealing with the subjects of inheritance, early life, college years, medical training, personality and career. Two chapters are devoted to Southard's work as a pathologist and neuropathologist. Individual chapters deal with Southard as a state officer, as the director of the Boston Psychopathic Hospital, in psychiatric social work, as an etymologist, philologist, philosopher and psychologist and as an educator and psychiatrist.

In the course of the narration, Dr Gay sketches much of the history of psychiatry in its broadest aspects during the important period 1910-1920, and all who have an interest in this subject will find much of value. In the minds of those who worked in this field during that period, the challenge of Southard's view will again be brought to life. To those of the newer generation much background material will be uncovered.

How well has Dr Gay wrought? This is a hard question for the reviewer — an old disciple of a revered chief — to answer. If Dr Gay succeeds in impressing the reader with the extraordinary influence that Southard had on his students and associates, he will have accomplished a great deal. It is obvious that no biographer can seem completely adequate to one who lived close to Southard and was under his influence for years. But unquestionably it is a good biography. It is pleasant reading, it is anecdotal, it is valuable as a history of psychiatric thought, and it is a thoughtful portrayal of an important and interesting personality.

*Teachable Moments A new approach to health* Jay B. Nash 243 pp New York A. S. Barnes & Co., 1938 \$1.50

From the publisher's blurb one might assume that this is an epoch making treatise on the subject of health training. It is not. Dr Nash is not a physician, he is a popular teacher of physical education, and aiming at popularity, is rather given to oversimplification and the employment of catchwords and phrases. Yet his dos and don'ts of health, though in no sense new, are sound on the whole, and he has not permitted himself to become the propagandist of this or that fad or cult. His book may be recommended with safety if not with enthusiasm.

*The New International Clinics* Original contributions clinics, and evaluated reviews of current advances in the medical arts. Edited by George M. Piersol. Vol. 4, N S 1 350 pp Philadelphia, Montreal, New York J. B. Lippincott Co., 1938 \$3.00

The fourth volume of the *New International Clinics* upholds the standard set by previous contributions. There are a number of original contributions on a wide variety of topics. In addition, three reports from clinics are given and one review. This review is perhaps the most important article in the whole volume, being a complete summary of our knowledge of the so-called Cushing's syndrome, with an extensive bibliography. In addition, there are good articles on the placenta, polyneuritis, vitamin B<sub>1</sub> in the American diet, hypertension, and the length of life of cardiac cases. The volume, as usual, is well illustrated by both pictures and diagrams, and the bibliographies are carefully chosen.

## THE TREATMENT OF GOUT WITH A LOW-FAT, HIGH-CARBOHYDRATE DIET\*

### Preliminary Report

ELMER C. BARTELS, M.D.†

BOSTON

A REVIEW of the literature pertaining to the treatment of gout is likely to lead one to the conclusion that it is not amenable to complete control. In this disease great emphasis has been placed on the treatment of the acute arthritic episodes and little on their prevention. It must be accepted that once a patient has gout he continues to have a metabolic defect, and that repeated attacks make for chronic degenerative changes in the joints and visceral organs. It is as though in diabetes the treatment of coma were stressed and little attention were given to its prevention. In a recent article by Talbott and Coombs<sup>1</sup> the following statement was made:

It is our belief that there is no known cure for gout and that once the diagnosis is confirmed the disease will persist until the patient dies. On the other hand, much may be done to afford symptomatic relief especially during acute attacks, when rest in bed, abundant fluids and a soft diet are indicated. The treatment of gout during arthritis-free periods has been and continues to be a subject for argument. Innumerable regimens and diets have been proposed, the merits of which are difficult to evaluate.

They reported 2 cases which tended to show that a diet low in protein and purine was not specific in the treatment of this condition.

Cohen,<sup>2</sup> in a review of 37 cases of gout from the Philadelphia General Hospital between 1929 and 1935, reported that the treatment was invariably satisfactory on a purine-free diet and colchicine. He stated, however, that in cases in which the uric acid level was elevated this elevation continues or increases. Herrick and Tyson<sup>3</sup> reported 6 cases of gout treated by a low-purine diet and colchicine. Of those cases in which follow-up determinations of the uric acid in the blood were taken, 3 returned to normal and 1 was reduced from 8 to 5 mg per cent. In the report of the *Fourth Rheumatism Review*<sup>4</sup> it was stated

that the usual therapy during the attack consisted of rest in bed, protection of joints, hot compresses, purgation, colchicine, cinchophen or salicylates and alkalies, a diet high in carbohydrate and non-purine-containing proteins, low in fats and free of purines. Treatment between attacks included purine restrictions, avoidance of alcohol and the intermittent use of certain drugs.

In England, where gout is relatively frequent, Kersley,<sup>5</sup> physician to the Royal National Hospital for Rheumatic Diseases, subdivided treatment into general hygiene, internal medication and physiotherapy. Under the first is included a diet low in purine and void of beverages such as strong tea, coffee or cocoa, meat extracts and all forms of alcohol, the total caloric value is reduced by cutting down carbohydrate and fat. Colchicine in the acute attack and cinchophen in the chronic state were administered periodically, three days a week.

In the acute episode, Keefer<sup>6</sup> utilizes a diet high in protein and carbohydrate but low in fat and purine. Fluids are forced and wine of colchicum and tincture of rhubarb are given until diarrhea results. He states that the treatment of chronic gout continues to be unsatisfactory and that further investigation of the disease is needed.

Jacobson<sup>7</sup> has proved that a purine-free diet alone is not effective in the treatment of gout, if one is to judge control of this disease by the level of the serum uric acid. He reports that the consumption of a purine-free diet during periods shorter than three months does not significantly influence the level of the uric acid. He also found in 4 cases an apparent direct correlation between the height of the serum uric acid level and the severity of the disease. Of sixty-one serum uric acid determinations on 5 patients who were free of acute attacks of gout on a purine-free diet, only one value was below normal, and of fifty-one determinations on 6 patients during acute gout on a similar diet and, in addition, medication consist-

\*From the Department of Internal Medicine, Lahey Clinic, Boston.  
†Physician, Department of Internal Medicine, Lahey Clinic.

ing of aspirin and colchicine, none of the values fell below 7 mg per cent (normal, 6 mg per cent). However, whole blood uric acid decreases of a slight degree have been reported by some authors after the prolonged use of a purine-free diet.

Lockie and Hubbard<sup>8</sup> (1935) proposed the use of a high-carbohydrate, low-fat diet for the treatment of gout. They gave diets high in fat to 4 patients and in each case an attack occurred in a few days. On a low-fat, high-carbohydrate diet the symptoms were relieved in a short time. They concluded that diets high in fat and low in carbohydrate should be avoided in the treatment of gout. Relief was also obtained in patients with severe joint pain by the intravenous injection of 100 to 200 cc of a 50 per cent solution of glucose. We have utilized this procedure during acute attacks, with gratifying results. This experience with production of acute attacks by a high-fat intake was suggested as a provocative test for gout. If in five to seven days after the institution of such a diet pain occurred, a diagnosis of gout could be considered.

Pisani,<sup>9</sup> of Florence, has independently observed that gout is easier to control if an intake high in carbohydrate is maintained. He also resorted to the use of glucose, orally, rectally and intravenously, according to the activity of the disease.

It is our purpose in this preliminary report to demonstrate that gout can apparently be controlled from both the standpoint of symptoms and the level of blood uric acid. The plan of treatment consists of the utilization of a diet high in carbohydrate and low in fat and purine, with the addition of the periodic administration of cinchophen. The diet used is that proposed by Lockie and Hubbard<sup>8</sup> and the cinchophen is given according to the plan of Hench,<sup>4</sup> 7½ gr three times a day for three days each week.

In the early part of the study, uric acid determinations were done on the whole blood, a normal determination being below 4.5 mg per cent. Since the report of Jacobson<sup>7</sup> on the determination of the uric acid in the serum we have used the two methods, and thus have a check, the normal level of uric acid in the serum being 6 mg per cent.

#### CASE REPORTS

**Case 1** A 61-year-old, unemployed watchman was first seen at the clinic in June, 1937. He had had rheumatism of 15 years duration. The condition began with periodic attacks of painful swelling of a toe, ankle or knee, which came on suddenly, were severe for several days at a time and subsided without residual discomfort. Soon the attacks came more often, and grew more severe in that they lasted longer and more joints were involved. In the previous

3 years he had suffered continuously from pain and swelling in the right arm, shoulder and neck and had had to be in bed for weeks at a time, being incapacitated to the point that he could not feed himself.

Physical examination revealed a well-developed man who weighed 160 pounds. The joints of the extremities were enlarged and limited in motion and all movements were done with great discomfort. A pea sized white mass was found in the pinna of the left ear. The value for the blood uric acid was 7.5 mg per cent. A roentgenogram of the hand showed marked hypertrophic changes around the interphalangeal joint and the metacarpophalangeal joints. There was partial loss of the joint space. A diagnosis of gout was readily made. Of particular interest was the fact that in the 15 years of his illness the patient had never been told that his trouble was gout.

Treatment was instituted, consisting of a high-carbohydrate, low purine, low fat diet with the addition of cinchophen. Sixteen months have now passed since the beginning of treatment. The patient has had no further attacks of gout and although his clinical course at first was slow, at the present time he states, "I feel perfectly well and have had no discomfort for 10 months, after being in misery for 8 years."

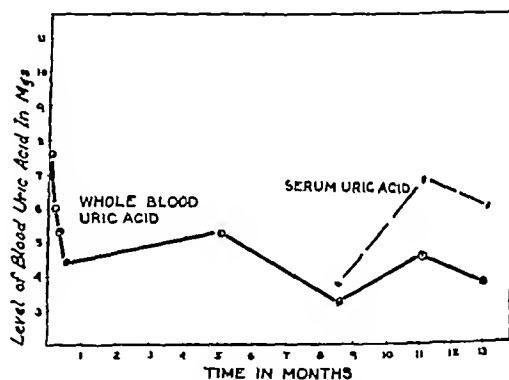

FIGURE 1 Case 1 Uric Acid Determinations before and during Treatment

Figure 1 gives the course of the uric acid determinations. One month after institution of treatment the level of uric acid was within normal limits. At 5 months it was only slightly above normal. A rise at the 11th month was thought to be due to a daily intake of beer.

**Case 2** A 54-year-old millwright was first seen in March, 1938. He was well until 5 months previously, when he had suffered an attack of pain in the right ankle. The pain came on suddenly one afternoon, and by night the weight of the bed clothing could not be borne on the foot. He was out of work 7 days, and by the end of 10 days his foot was normal. The second attack came on 1 month before he came to the clinic. It started in the left great toe and was followed the next day by involvement of the left knee. He suffered severely for 2 weeks and then gradually obtained relief.

On physical examination the patient was found to be obese, weighing 201 pounds. The only other finding of note was a violaceous swelling over the left great toe, with tenderness over the medial aspect. The significant laboratory finding was a uric acid determination of 8.4 mg per cent on the whole blood and 8.8 mg per cent on the serum. A roentgenogram of the great toe showed no bony change.

A diagnosis of gout was made and treatment instituted. It is now 7 months since the beginning of treatment. The patient has had no recurrence of his gouty episodes, and the level of the blood uric acid has remained within normal limits, as shown in Figure 2

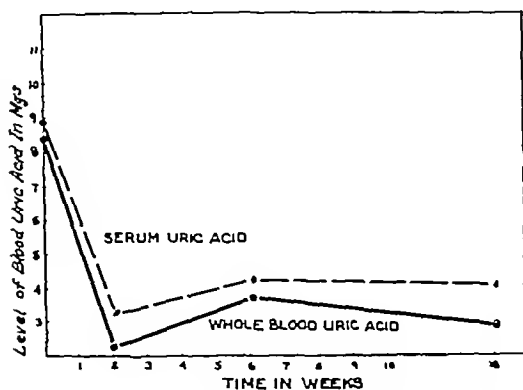

FIGURE 2 Case 2 Uric Acid Determinations before and during Treatment

*Case 3* A 39-year-old, Jewish salesman was first seen in March, 1938. He had had recurring attacks, eight in all, of acute joint pains during a period of 5 years. The attacks came on suddenly and involved the feet, ankles or knees. In 24 hours the pain and swelling were severe enough to force him to bed and incapacitate him for 1 or 2 weeks. He suffered no residual discomfort after the attack subsided. The last attack began 2 weeks previous to his examination when the right elbow became painfully swollen

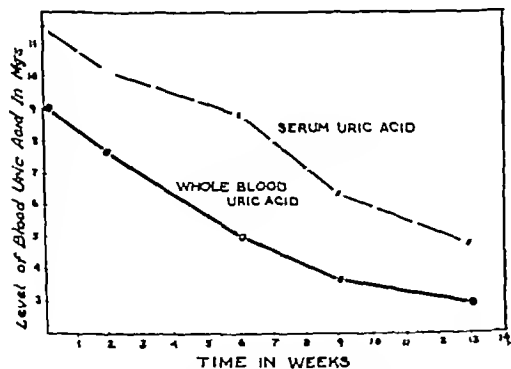

FIGURE 3 Case 3 Uric Acid Determinations before and during Treatment

and red, a day or so later the left foot was involved. His condition was improving when he was first seen at the clinic.

Physical examination revealed that the patient was short and stocky, weighing 174 pounds. The findings of note were in the right elbow and left foot. These joints were hot, red and painful to touch or forced motion. There was a white mass the size of a pea in both ears. A chemical test on the contents of one of these masses was positive for uric acid. The uric acid determination on the whole blood was 9.1 mg per cent and that on the serum 11.7 mg per cent. A roentgenogram of the foot revealed no abnormality.

A diagnosis of gout was made and treatment with the afore mentioned diet and cinchophen was instituted. During the following 3 months the patient had no further attacks, and Figure 3 shows a drop of the level of uric acid to normal.

*Case 4* A 63-year-old naval officer was first seen in 1934. He had had three attacks of severe pain and swelling in one or the other great toe during the previous 10 years, the last one occurring 5 weeks before he came to the clinic. Relief was usually obtained by application of heat and rest of the foot. He had never suffered residual discomfort. Examination at that time showed him to be well developed but only fairly well nourished. The left great toe on its medial aspect was distinctly cyanotic and tender.

The uric acid determination on the whole blood was 5.4 mg per cent. A diagnosis of gout was made and wine of colchicum was prescribed. Local measures were also advised. Three days later the foot was normal and

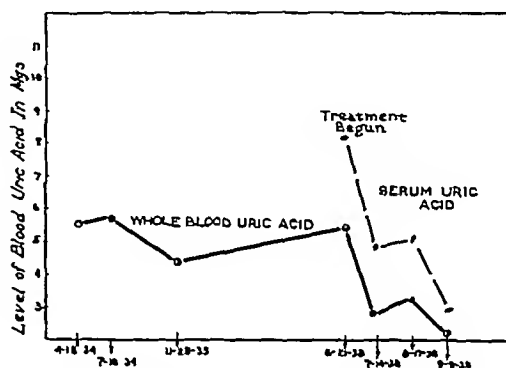

FIGURE 4 Case 4 Uric Acid Determinations before and during Treatment

the colchicum was discontinued. He returned 20 months later for a check up examination, he had not had any attacks in the interim. His physical examination was normal and the level of the blood uric acid was normal, being 4.3 mg per cent. At that time he was advised to take a low purine diet. He was seen periodically after this because of some mild functional gastrointestinal symptoms. In March, 1938, he had a recurrence of his gout, the right great toe being involved, the acute phase lasting 6 weeks. At the time of his examination in June there was still some residual tenderness of the right great toe. The uric acid determination on the whole blood was 5.2 mg and on the serum 8.1 mg. Treatment as used in the previous cases was begun. He has now been symptom free for 2½ months. Figure 4 reveals the fall in the value for blood uric acid to normal.

#### COMMENT

The 4 cases reported illustrate our experience with the treatment of gout by a medical regimen consisting of low purine, low-fat and high-carbohydrate diet, with the administration of cinchophen. In these cases the plan accomplished the desired effects: prevention of further attacks of joint pain, and return of the blood uric acid to a normal level. The low-fat high-carbohydrate diet is not difficult to prepare and its satiety value is quite satisfactory.

The general directions for the diet are shown in Table 1. The amount of meat, fish or fowl to be

utilized depends on the severity of the disease. These foods contain some purine but must be included to satisfy the patient. At the onset of treatment they are restricted to one serving two or three days a week, and are given more frequently until being given daily if the uric acid level permits. The sample menu contains 278 gm of carbohydrate, 77 gm of protein and 22 gm of fat, with a caloric content of 1618 calories. The amount of carbohydrate is increased in order to obtain

the caloric requirement for the patient. Because the diet is inadequate in vitamins A and B<sub>1</sub>, haliver oil and thiamin chloride must be supplemented. Patients frequently lose weight in the beginning of treatment until they learn to consume sufficient carbohydrates to make up for the calories lost in the elimination of fat from the diet.

Many authors have feared the continued use of cinchophen because of its possible toxic effect on the liver. We agree with Hench,<sup>4</sup> who believes that the danger of cinchophen is far less than has been feared, that it is more a matter of individual susceptibility of rare occurrence than of a universal poison, and that the benefit from its careful use outweighs its possible harmful effects. The high-carbohydrate diet may tend to act as a guard against any toxic action on the liver. Needless to say, patients at the onset of treatment are advised to discontinue the cinchophen if they notice any ill effect such as an irritation or discoloration of the skin or stomach distress. Cinchophen plays its role by increasing the uric acid excretion in the urine. Recent work by Grabfield<sup>10</sup> suggests that this action is on the sympathetic nerves which supply the kidneys.

## SUMMARY

Four cases of gout are presented in which symptomatic relief and a falling of the blood uric acid to normal were obtained by a plan of treatment consisting of a low-purine, low-fat, high-carbohydrate diet, with cinchophen. These results warrant further investigative utilization of such a plan in a larger series of patients.

## MENINGITIS SECONDARY TO SUBACUTE BACTERIAL ENDOCARDITIS\*

WILSON F. SMITH, M.D.†

HARTFORD, CONNECTICUT

**M**ENINGITIS occurring during the course of subacute bacterial endocarditis has been reported from time to time, but is by no means a commonly recognized complication of this disease,‡ so frequently punctuated by embolic phenomena. When the long list of conditions with which this form of endocarditis has been confused is compiled, meningitis is rarely included. Blumer,<sup>1</sup> in his excellent monograph on subacute bacterial endocarditis, enumerates twenty-one diseases which must be considered in a differential diagnosis, but meningitis is not mentioned. The present paper summarizes the 32 cases of meningitis secondary to subacute bacterial endocarditis which are recorded in the literature, and adds 3 new ones which emphasize this little-recognized manifestation of a disease well known for its protean symptomatology.

### REVIEW OF THE LITERATURE

A few well-known authors have mentioned the possibility of meningitis or meningitic symptoms that occur during the course of subacute bacterial endocarditis. Osler,<sup>14</sup> in 1909, while discussing chronic infectious endocarditis spoke of cases showing predominant meningitic symptoms, but went into no further detail. In 1917 Debré<sup>5</sup> divided subacute bacterial endocarditis into ten "formes," the sixth of which was called the "nervous" type with meningitic or spinal symptoms. Tice<sup>15</sup> in his *Practice of Medicine* writes of the cerebrospinal manifestations of this disease, characterized chiefly by headache. He mentions embolic meningitis and says that "in a few instances the *Streptococcus viridans* has been cultured from the spinal fluid." When in 1923 Blumer<sup>1</sup> summarized the causes of death in 193 patients with subacute bacterial endocarditis, he found that only 2 of them had terminal symptoms of meningitis. Finally in 1925 Libman,<sup>9</sup> discussing the prognosis in subacute bacterial endocarditis, stated in a footnote that meningismus was a much neglected but valuable symptom of

this disease. Seven years earlier he<sup>8</sup> had shown how extensive hemorrhages into the brain, ventricles or subarachnoid space might occur from rupture of embolic aneurysms and how these hemorrhages could produce a symptom complex resembling meningitis, but with a bloody spinal fluid. Other textbooks and monographs recognize meningitis as a complication of acute bacterial endocarditis when the staphylococcus, pneumococcus or hemolytic streptococcus is the causative organism, but they fail to mention meningitis occurring during the course of subacute bacterial endocarditis caused by *Streptococcus viridans*.

When the literature is searched for reports of cases of meningitis secondary to subacute bacterial endocarditis, only 32 cases can be found. Many of these are incomplete, lacking bacteriological findings or adequate history. Autopsies are reported on only 11 cases. One of the earliest reports, by Claude<sup>4</sup> in 1918, was that of a boy who developed meningitic signs during the course of endocarditis. The spinal fluid contained many polymorphonuclear leukocytes, and at autopsy, evidence was found of a mild meningitis with underlying softening of the brain. Streptococci were found in the vegetations on the heart valves.

Oille, Graham and Detweiler<sup>13</sup> in 1915 first identified *Streptococcus viridans* in the spinal fluid in a case of meningitis secondary to subacute bacterial endocarditis. From then on, sporadic cases are found in the literature (Table 1) until Neal and her colleagues<sup>12</sup> in 1936 published a large series of cases which they had seen in consultation because of their resemblance to cases of epidemic meningitis, poliomyelitis or encephalitis. Fifteen of their cases had meningitic symptoms alone and 3 had them in combination with paralyses. In 5 cases *Streptococcus viridans* was cultured from the spinal fluid, 4 had signs of meningeal irritation from subarachnoid hemorrhage, and 2 of these proved to be meningismus—signs of meningeal irritation without any abnormal findings in the cerebrospinal fluid. It is only because the authors were specialists in meningitis and saw many cases in consultation that they were fortunate enough to examine so large a group of this little recognized complication of subacute bacterial endocarditis.

The following 3 cases are of interest because in 1 the meningitic symptoms twice developed while

‡Clinical assistant in medicine, Hartford Hospital, formerly resident physician, Second (Cornell) Medical Division, Bellevue Hospital and instructor in medicine, Cornell University Medical College.

In commenting on Case 24391 of the Case Records of the Massachusetts General Hospital (*New Eng. J. Med.* 219:498-494, 1938) Dr. Paul D. White writes: "This is the first case of subacute bacterial endocarditis that I have known to have been complicated by a meningitis; the cases seen at this hospital that have shown more clear proof should be reported in the literature which as yet has little to say on the subject."

the patient was under observation for other manifestations of subacute bacterial endocarditis, and in the other 2, meningitis was the first recognized symptom of a bacteremia which was not suspected until after treatment had been instituted, for meningococcus meningitis in 1 case and tuberculous meningitis in the other

#### CASE REPORTS

*Case 1* R. H. (No 104738), a 41 year-old, white woman, had always been well until December, 1934

day she was readmitted in a stuporous condition to one of the urological services of the New York Hospital, where at first uremia was suspected.

Examination on admission showed a thin, acutely ill woman, who was drowsy and delirious. She could be roused with difficulty and then her only complaint was headache. The temperature was 104°F, pulse 138, and respirations 28, full and deep. Two petechial hemorrhages were found in the left lower conjunctival sac, and there was blurring of both optic disks. The neck was stiff. A few rales were heard at the apex of the left lung. The heart was not enlarged, but a systolic murmur was heard, localized at the apex. This murmur had been

(7 months before her first admission), when she began to lose weight, be easily fatigued and to act strangely, becoming very religious and neglecting her family. She became depressed and at times irrational. She had periods of vomiting and in a few months developed ankle edema. Her family physician, telling her that she had a fever and heart trouble, put her to bed. Finally on July 27, 1935, she came to the New York Hospital clinic, complaining chiefly of urinary frequency, nocturia and dysuria. She had lost over 40 pounds during that spring. Hospitalization was advised, and after necessary study, renal tuberculosis was diagnosed and a left nephrectomy was performed. X-ray study of the chest at that time was negative for tuberculous infiltration, but tubercle bacilli were demonstrated in the removed kidney.

The patient made an uneventful recovery and went home. One month later, October 23, 1935, she suddenly became weak and lapsed into unconsciousness. The next

present during the previous admission. The liver edge was 6 cm below the costal margin, but the spleen could not be felt. Tendon reflexes were symmetrically hyperactive and there was a positive Kernig sign bilaterally, as well as a Brudzinski neck sign.

Examination of the urine showed 2+ albumin with many white cells and a few red cells in the sediment. Tubercle bacilli were subsequently isolated from the urine, but only by guinea pig inoculation. There was a hypochromic anemia with 3,100,000 red-blood cells and 53 per cent hemoglobin, and a moderate leukocytosis (12,000) with 60 per cent adult and 15 per cent immature polymorphonuclears. The blood Wassermann was negative and the nonprotein nitrogen 32 mg per cent. The cerebrospinal fluid was under increased pressure and contained 200 white cells, 90 per cent of which were polymorphonuclears. The sugar content of the spinal fluid was reduced to 39 mg per cent, and the total protein was

increased. No organisms could be demonstrated by smear or culture of the spinal fluid. A portable x-ray of the chest showed a diffuse mottling with miliary distribution. From these observations it was thought that the patient had miliary tuberculosis with tuberculous meningitis, and she was transferred to the tuberculosis service. Repeated spinal drainage was the only form of therapy, and in a few days she became rational and the signs of meningeal irritation gradually disappeared. She continued, however, to have a low grade fever. Neurological examination during the 2nd week in the hospital disclosed stiffness of the left arm with marked astereognosis of the left hand as well as definite mental changes. It was supposed that she had a brain abscess in the right parietal lobe. An x-ray of the chest taken during this week showed complete disappearance of the mottled shadows seen on admission. At the end of the 2nd week the first positive blood culture report was received,—a non hemolytic streptococcus,—but it was not until the end of the 6th week that more petechiae appeared and the

culosis and the presence of miliary mottling on x-ray of the lungs. Subacute bacterial endocarditis was not diagnosed until the blood culture showed non hemolytic streptococci. The subsequent course was characteristic in the development of a palpable spleen and the appearance of petechiae—two of which had been noticed on admission, although their true significance was not realized. The autopsy showed a bacterial endocarditis and evidence of a meningitis as well as bilateral areas of softening in the brain.

*Case 2* W. D. (No 67597) a 16-year-old schoolboy, was admitted to the Second (Cornell) Medical Division, Bellevue Hospital, August 22, 1936, complaining of severe headache of 3 days duration. During the previous month he had suffered from frequent attacks of frontal headaches associated with generalized malaise. Three days before admission the headache became more severe and he had sensations of chilliness. The following day he lost his appetite, vomited twice and for the first time complained of a stiff neck. On the day of admission the stiffness of the neck became more marked and the headache unbearable, and slight noises became very irritating.

On admission to the hospital the patient appeared acutely ill, lying in a position of opisthotonus, extremely irritable and overactive. He was moaning and talking incessantly. His temperature was 104°F, pulse 92, and respirations 34. The skin was clear and no petechiae were found. The heart was markedly enlarged to the left, the apical impulse being at the anterior axillary line in the 7th interspace. The first apical sound was loud and slapping and was followed by a rough systolic murmur. A diastolic rumble with presystolic accentuation was heard at the apex. The second pulmonic sound was accentuated. The liver and spleen were not felt. The tendon reflexes were symmetrically equal. Distinct neck Brudzinski and bilateral Kernig signs were present.

Urinalysis was normal except for a few red cells and leukocytes in the standing sediment. The blood count showed no anemia and 16,000 white cells, of which 68 per cent were adult and 20 per cent immature polymorphonuclears. An electrocardiogram revealed only a sinus tachycardia and notching of the P waves, often seen in association with mitral stenosis. A chest x-ray film showed a diffusely enlarged heart of a shape characteristic of double mitral valvular disease.

A lumbar puncture done shortly after admission produced a turbid, gray spinal fluid under increased pressure. It contained 1600 white cells, chiefly polymorphonuclears. The culture of this and of all subsequent spinal fluid specimens was negative, but direct smear of the first specimen showed a few cocci in pairs and chains. These were never found again. A blood culture taken on admission remained sterile. The preliminary diagnosis was rheumatic heart disease and epidemic meningitis.

The treatment consisted of spinal drainage twice a day and the administration of antimeningococcus serum, a total of 260 cc. being given intrathecally during the first 4 days. For the next 4 days spinal drainage was done once daily and no further serum was given. During the first 4 days the temperature gradually fell to a level between 101 and 102°F, where it remained for the rest of the course. The patient improved symptomatically in a few days.

In spite of the disappearance of meningeal symptoms, fever around 102°F persisted. Tenderness of the finger-nails developed, but blood cultures were negative until September 15, 3 weeks after admission when *Streptococcus viridans* was first isolated. This was confirmed on six subsequent cultures taken from nose to time until death. The patient had no further symptoms except occasional

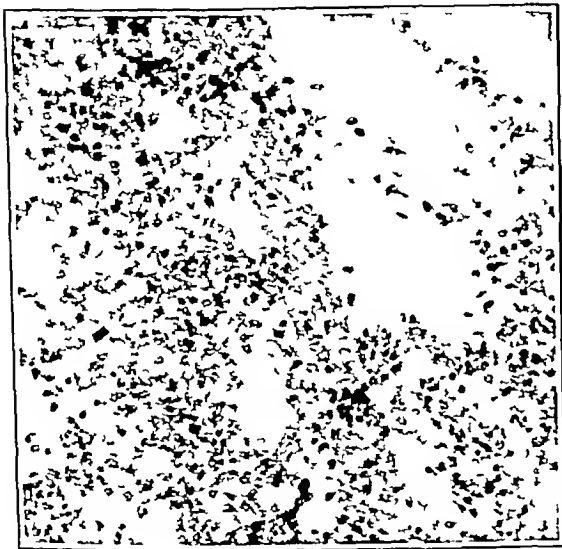

FIGURE 1 Case 1

Section of brain showing meningitis with cellular exudate containing polymorphonuclear leukocytes and round cells (X 185)

spleen was first felt. The patient's course was slowly downhill, the temperature rising almost daily to 103°F. On the 53rd hospital day she suddenly became paralyzed on her right side and died 4 days later. At autopsy the pertinent findings were vegetative endocarditis of the mitral and aortic valves (non hemolytic streptococcus, gamma type), infarcts of the kidney, spleen and left lung, purulent meningoencephalitis, fibrous calcified scars in the upper lobes of both lungs and tuberculosis of the bladder and left ureter. The pia arachnoid membrane was thickened and bulky over both hemispheres of the brain, and there was distinct encephalomalacia in the areas of the right and left insulae. Microscopic examination (Fig 1) showed meningitis with a cellular exudate containing polymorphonuclear leukocytes. Associated with this condition was encephalitis with collections of small round cells in the perivascular spaces of some of the cortical vessels.

*Comment* This case was diagnosed as tuberculous meningitis in the light of a recent nephrectomy for tuber

periods of tenderness of the fingertips, lasting a few days each until October 13, when a bout of severe generalized abdominal pain, accompanied by vomiting and a chill, suggested either splenic or mesenteric infarction. This condition subsided spontaneously after a few days and the patient was fairly comfortable until October 28, 2 months after the subsidence of the meningitis, when he developed a right hemiplegia. From this point on, the course was steadily downhill, in spite of an intensive course of bacteriophage given intravenously twice daily for 1 month. Petechiae appeared sporadically, and the spleen became palpable. Just before death the patient developed signs and symptoms of a fresh intracranial accident. He died on December 8, the 108th hospital day. Permission for autopsy was refused. Incidentally, Dr Josephine Neal saw this case in consultation after the positive blood culture had been reported, and she agreed that the meningitis was probably secondary to a pre-existing subacute bacterial endocarditis.

**Comment** This patient entered the hospital because of meningitic symptoms and was treated on a presumptive diagnosis of meningococcal meningitis until 20 days after admission, when blood cultures first showed *Streptococcus viridans*. The subsequent course was typical of subacute bacterial endocarditis. Intensive bacteriophage therapy did not alter the fatal course.

**Case 3** M S (No 93693) a 19 year-old Negress, was admitted to the Second Medical Division, Bellevue Hospital, July 20, 1937, complaining of joint pains of 3 or 4 months' duration. She first had rheumatic fever at the age of 7, at which time she was a patient in Harlem Hospital. At 8 and at 11 she suffered from recurrent bouts of polyarthritides with fever. During her first illness she was told that she had heart trouble, and although she never had dyspnea or ankle edema, she was kept out of gymnasium at school. Her tonsils were removed at the age of 11.

In March, 1937, the patient began to have migratory joint pains, but continued her work as a student. Toward the end of June she had a tooth extracted. One week later she went to bed with a headache, fever and precordial pain not related to exercise. On July 13, 1937, she was admitted to the Hospital for Joint Diseases because of the pains in her legs. Severe pain in the right calf, radiating to the foot, suddenly developed, and this was her chief complaint when she was transferred to Bellevue Hospital 1 week later.

Examination on admission showed a well-developed and well-nourished Negress with a moderate fever. She appeared acutely ill. One petechial hemorrhage was found in the lower right conjunctival sac. The heart was enlarged to the left, systolic and diastolic thrills were felt at the apex, where the apical impulse was diffuse and heaving. A harsh systolic murmur radiating to the left axilla was heard at the apex, where there also was a localized crescendo presystolic murmur. There was spasm and tenderness in the left upper quadrant of the abdomen, though no masses or viscera were felt. There was tenderness in the right calf and the right dorsalis pedis pulse was absent. Tendon reflexes were hyperactive and symmetrical. The diagnosis on admission was subacute bacterial endocarditis, with arterial embolism in the right leg.

Examination of the urine was normal except for a few red cells. The blood count showed a moderate anemia and 6300 white cells, with 64 per cent adult and 18 per cent immature polymorphonuclears. The blood Wassermann was negative, and the electrocardiogram showed only

a sinus tachycardia. An x-ray film of the chest showed a diffusely enlarged heart.

The temperature rose daily to about 103°F. The pain in the right calf gradually subsided, and after a few weeks the dorsalis pedis pulsation returned. Transient petechiae were noted, and there were occasional sharp pains over the spleen. Repeated blood cultures, however, were negative until August 10, 3 weeks after admission, when *Streptococcus viridans* was isolated.

Two days later the patient became drowsy, vomited twice and complained of occipital headache. She developed a stiff neck and a positive Kernig sign bilaterally, and the temperature rose to 105.4°F. Meningitis was diagnosed. Lumbar puncture produced a cloudy pink fluid under increased pressure. The fluid contained 3800 white cells, 90 per cent of which were polymorphonuclears. *Streptococcus viridans* was isolated from this fluid by

FIGURE 2 Case 3

Section of cerebral cortex showing meningitis with infiltration of polymorphonuclear leukocytes and round cells as well as local edema (X 200)

smear and culture. The patient was given sulfanilamide by mouth and daily spinal drainages, under which regimen the spinal fluid gradually became clear, the temperature dropped until it was normal by August 23 (11 days after the onset of the meningitis), and the stupor gradually cleared. The girl was then up in a chair and afebrile, with transient diplopia her only complaint, until October 16. At that time blood cultures again became positive for *Streptococcus viridans*, and painful spots developed in the fingertips and toes—Osler's nodes. On November 9, nearly 3 months after the first attack of meningitis, the patient again developed signs of meningeal irritation and became febrile and stuporous. The spinal fluid was cloudy and contained 2000 leukocytes, 80 per cent being polymorphonuclears. In spite of the repeated use of sulfanilamide the patient died on November 14, the 119th hospital day.

At autopsy the pertinent findings were vegetative endocarditis of the mitral valve and adjacent area in the left auricle, infarcts of the spleen and kidneys, and evidence of old meningitis and recent hemorrhage in the brain. The

leptomeninges on the dorsal aspect of the right temporal lobe, right frontal lobe and optic chiasm were dull and finely granular. There was subarachnoid blood between the cerebellum and the medulla. In the right parieto-occipital region there was a depression and an area of softening about 8 cm in diameter. On sectioning, this was found to contain about 75 cc of firmly clotted blood. There was clotted blood in both lateral ventricles and in the aqueduct of Sylvius, but not in the spinal canal. Microscopic examination (Fig 2) showed a meningitis with infiltration of polymorphonuclear leukocytes and round cells as well as local edema.

**Comment** This is a definite case of subacute bacterial endocarditis which, while on the ward, developed a *Streptococcus viridans* meningitis which was apparently cured by sulfanilamide and daily spinal drainage. The patient was well for two months before another episode with meningitic symptoms appeared and proved fatal. Autopsy showed typical findings of subacute bacterial endocarditis with visceral infarcts. The brain showed evidence of an old basilar meningitis, encephalomalacia and recent subarachnoid hemorrhage.

#### DISCUSSION

The mechanism by which meningitis is produced in subacute bacterial endocarditis probably is fairly simple. Small pieces of vegetation or masses of bacteria from the heart valve break loose and are carried in the blood stream to the vessels of the brain. Here mycotic (infected) aneurysms may form, either from involvement of the vessel wall or of the wall of the artery directly from its lumen. These aneurysms may rupture, causing a hemorrhage into the brain substance or into the subarachnoid space. Then the presence of blood in the cerebrospinal fluid produces meningeal irritation. On the other hand, the emboli from the heart may produce thromboses of the smaller or larger vessels of the brain, and around these areas encephalomalacia occurs, either from invasion of leukocytes or from actual multiplication of organisms. This process varies from slight softening to complete destruction and formation of abscesses. If one of these infarcted areas should rupture into the subarachnoid space, organisms may be found in the spinal fluid, showing that a true bacterial meningitis exists. Even without rupture, meningeal irritation may occur in the membranes over a superficial area of softening, and a localized meningitis may be produced with bacteria appearing in the spinal fluid. Finally, congestion of the pia arachnoid membrane may arise secondary to more deeply located infarcts, producing a serous meningitis with no organisms in the spinal fluid.

One of the interesting features of bacterial meningitis secondary to subacute bacterial endocarditis is that it usually subsides spontaneously, or in spite of any treatment. This is probably because the causative organisms are of low virulence and are easily overcome by the local defense mecha-

nisms. Were it not for the growth of bacteria on an already damaged heart valve, the body would doubtless be able to handle the bacteremia successfully. In most cases where meningeal symptoms immediately precede death in subacute bacterial endocarditis, as in the second episode in Case 3, they are caused by a hemorrhage, rather than being true bacterial meningitis. In this case it is hard to believe that sulfanilamide had anything to do with the subsidence of the first meningeal episode, and it is easy to see why it had no effect on the terminal meningitis which autopsy showed was caused by blood in the subarachnoid spaces.

Subacute bacterial endocarditis should be kept in mind when in a case of meningitis a heart murmur is present, petechiae are found and a cloudy spinal fluid contains no demonstrable organisms. (This does not alter the rule, however, that antimeningococcus serum should be given empirically to every case of meningitis with a cloudy spinal fluid until culture shows that some organism other than meningococcus is the cause. Further experience with sulfanilamide may change this rule.) In the first case presented, the circumstantial evidence of a recent nephrectomy for tuberculosis of the kidney and a suggestive portable chest x-ray film directed the diagnosis toward tuberculous meningitis, although the spinal fluid was not typical of this disease and although petechial hemorrhages and a systolic heart murmur had been noted. In the second case, a mitral stenosis was diagnosed on admission, but the importance of the chains of cocci in the spinal fluid was minimized until twenty days later, when the blood culture first showed a streptococcus. In atypical cases of meningitis, therefore, a correct diagnosis may sometimes be reached early in the course, if subacute bacterial endocarditis is remembered as a possible cause.

#### SUMMARY AND CONCLUSIONS

Meningitis is an unusual manifestation of subacute bacterial endocarditis, although it has been recognized as such for many years.

Only 32 cases of meningitis secondary to subacute bacterial endocarditis have been reported.

Three additional cases are reported in this paper, 1 occurring during the classical course of subacute bacterial endocarditis, 1 with the admitting diagnosis of meningococcal meningitis, and 1 being admitted as tuberculous meningitis.

The pathologic processes by which meningeal irritation may be produced in subacute bacterial endocarditis are discussed briefly.

*Streptococcus viridans* meningitis in subacute bacterial endocarditis is usually of short duration and subsides spontaneously.

periods of tenderness of the fingertips, lasting a few days each until October 13, when a bout of severe generalized abdominal pain, accompanied by vomiting and a chill, suggested either splenic or mesenteric infarction. This condition subsided spontaneously after a few days and the patient was fairly comfortable until October 28, 2 months after the subsidence of the meningitis, when he developed a right hemiplegia. From this point on, the course was steadily downhill, in spite of an intensive course of bacteriophage given intravenously twice daily for 1 month. Petechiae appeared sporadically, and the spleen became palpable. Just before death the patient developed signs and symptoms of a fresh intracranial accident. He died on December 8, the 108th hospital day. Permission for autopsy was refused. Incidentally, Dr Josephine Neal saw this case in consultation after the positive blood culture had been reported, and she agreed that the meningitis was probably secondary to a pre-existing subacute bacterial endocarditis.

*Comment* This patient entered the hospital because of meningitic symptoms and was treated on a presumptive diagnosis of meningococcal meningitis until 20 days after admission, when blood cultures first showed *Streptococcus viridans*. The subsequent course was typical of subacute bacterial endocarditis. Intensive bacteriophage therapy did not alter the fatal course.

*Case 3* M S (No 93693) a 19 year-old Negress, was admitted to the Second Medical Division, Bellevue Hospital, July 20, 1937, complaining of joint pains of 3 or 4 months' duration. She first had rheumatic fever at the age of 7, at which time she was a patient in Harlem Hospital. At 8 and at 11 she suffered from recurrent bouts of polyarthritis with fever. During her first illness she was told that she had heart trouble, and although she never had dyspnea or ankle edema, she was kept out of gymnasium at school. Her tonsils were removed at the age of 11.

In March, 1937, the patient began to have migratory joint pains, but continued her work as a student. Toward the end of June she had a tooth extracted. One week later she went to bed with a headache, fever and precordial pain not related to exercise. On July 13, 1937, she was admitted to the Hospital for Joint Diseases because of the pains in her legs. Severe pain in the right calf, radiating to the foot, suddenly developed, and this was her chief complaint when she was transferred to Bellevue Hospital 1 week later.

Examination on admission showed a well-developed and well-nourished Negress with a moderate fever. She appeared acutely ill. One petechial hemorrhage was found in the lower right conjunctival sac. The heart was enlarged to the left, systolic and diastolic thrills were felt at the apex, where the apical impulse was diffuse and heaving. A harsh systolic murmur radiating to the left axilla was heard at the apex, where there also was a localized crescendo presystolic murmur. There was spasm and tenderness in the left upper quadrant of the abdomen, though no masses or viscera were felt. There was tenderness in the right calf and the right dorsalis pedis pulse was absent. Tendon reflexes were hyperactive and symmetrical. The diagnosis on admission was subacute bacterial endocarditis, with arterial embolism in the right leg.

Examination of the urine was normal except for a few red cells. The blood count showed a moderate anemia and 6300 white cells, with 64 per cent adult and 18 per cent immature polymorphonuclears. The blood Wassermann was negative, and the electrocardiogram showed only

a sinus tachycardia. An x-ray film of the chest showed a diffusely enlarged heart.

The temperature rose daily to about 103°F. The pain in the right calf gradually subsided, and after a few weeks the dorsalis pedis pulsation returned. Transient petechiae were noted, and there were occasional sharp pains over the spleen. Repeated blood cultures, however, were negative until August 10, 3 weeks after admission, when *Streptococcus viridans* was isolated.

Two days later the patient became drowsy, vomited twice and complained of occipital headache. She developed a stiff neck and a positive Kernig sign bilaterally, and the temperature rose to 105.4°F. Meningitis was diagnosed. Lumbar puncture produced a cloudy pink fluid under increased pressure. The fluid contained 3800 white cells, 90 per cent of which were polymorphonuclears. *Streptococcus viridans* was isolated from this fluid by

FIGURE 2 Case 3

smear and culture. The patient was given sulfanilamide by mouth and daily spinal drainages, under which regimen the spinal fluid gradually became clear, the temperature dropped until it was normal by August 23 (11 days after the onset of the meningitis), and the stupor gradually cleared. The girl was then up in a chair and afebrile, with transient diplopia her only complaint, until October 16. At that time blood cultures again became positive for *Streptococcus viridans*, and painful spots developed in the fingertips and toes—Osler's nodes. On November 9, nearly 3 months after the first attack of meningitis, the patient again developed signs of meningeal irritation and became febrile and stuporous. The spinal fluid was cloudy and contained 2000 leukocytes, 80 per cent being polymorphonuclears. In spite of the repeated use of sulfanilamide the patient died on November 14, the 119th hospital day.

At autopsy the pertinent findings were vegetative endocarditis of the mitral valve and adjacent area in the left auricle, infarcts of the spleen and kidneys, and evidence of old meningitis and recent hemorrhage in the brain. The

It is in this type that injection treatment is ideal. With increase in size the masses may become large enough to prolapse through the external sphincter. Sometimes internal and external piles are combined. In these cases the mucous membrane of the anal canal is undermined by varicosities and may slide down, to bring the pectinate line outside the anal orifice. Operative treatment is preferable for these patients.

Classification of the various types of hemorrhoids encountered in the clinic is given in Table 2. It

TABLE 2 *Classification of Cases*

DIAGNOSIS	NO. OF CASES
Internal hemorrhoids	25
Internal hemorrhoids thrombosed	3
External hemorrhoids	6
External hemorrhoids thrombosed	46
External thrombosis with external piles	12
Combined hemorrhoids	52
Total	136

can be seen that there was a great preponderance of uncomplicated internal hemorrhoids, the type suited to treatment by injection.

#### INCIDENCE

The highest incidence of hemorrhoids is between the ages of forty and fifty. This is shown in Table 3. Two hundred and thirty-four pa-

TABLE 3 *Age Distribution*

AGE	NO. OF CASES	AGE	NO. OF CASES
0-9	0	40-49	109
10-19	3	50-59	74
20-29	64	60-69	33
30-39	85	70-79	8
Total		234	

tients, or 62 per cent, were men, and 142 or 38 per cent, were women.

#### SYMPTOMS

Bleeding is the commonest symptom of internal hemorrhoids. It was present in 82 per cent of our cases, either alone or in combination with other symptoms. The blood varies in amount from a few drops to several ounces, is bright-red and not clotted, usually comes after a constipated movement and is due to the pressure of hard feces that breaks a varicosity. Invariably it stops spontaneously. In severe cases bleeding may be repeated with every movement for days, even weeks, the patient coming to the clinic with severe secondary anemia. This, however, is rare; there were not more than 2 or 3 of our patients who had noticeable secondary anemia from bleeding hemorrhoids—in 1 case the hemoglobin was 30 per cent.

Protrusion is the other common symptom of internal hemorrhoids, it was present in 46 per cent of our cases. It usually occurs during bowel movements, and in most of the cases is reduced spontaneously at the end of defecation. In more advanced cases, it has to be replaced manually by the patient, and in a few cases of combined external and internal hemorrhoids it remains unreduced. In these instances the patient complains of constant "leakage," which is due to mucous secretion from the exposed mucous membrane covering the prolapsed internal piles.

Pain is very rare in uncomplicated internal hemorrhoids. It was present in only 4 per cent of our cases. On the other hand, it is the main symptom of an external thrombosed pile and was present in every one of 55 such cases in our series. Pain is also very severe in cases with thrombosis of an internal pile accompanied by prolapse and strangulation. These cases, however, are not common.

Pruritus existed in about 2 per cent of the patients, but we believe this was a coincidence rather than a symptom of the disease. Constipation was present in an undetermined number, but cannot be considered as entirely due to the hemorrhoids.

#### TREATMENT OF INTERNAL HEMORRHOIDS

As previously mentioned, internal hemorrhoids are composed of a plexus of small, thin-walled vessels embedded in loose areolar tissue. They may be treated by injection or by surgery. The aim of injection treatment is to introduce an irritating solution into this areolar tissue which will spread around the thin-walled veins. This irritating substance causes an inflammatory reaction with swelling and subsequent proliferation of fibrous tissue. The swelling tends to obliterate the blood vessels, with resultant reduction in size of the hemorrhoid and relief from bleeding. Later contraction of scar tissue makes the result permanent or semi-permanent. Injection treatment does not always result in a cure.

*Technic of Injection.* The patient lies in the right Sims's position, and with his left hand elevates the left buttock, thus facilitating exposure of the anus. The operator sits on a stool at the side of the table facing the patient's buttocks, his line of vision level with the operative field. A student's stand lamp placed between the operator's feet and reaching the level of his chin supplies adequate illumination.

Digital examination is first performed, using the left index finger covered with a rubber cot. If an inflammatory lesion is found, such as a fissure, fistula or acute cryptitis, no injection should be

Subacute bacterial endocarditis should be thought of in the differential diagnosis of meningitis

## HEMORRHOIDS\*

### With Special Reference to Injection Treatment

ROY E. MABREY, M.D.,† AND GEORGE S. SPEARE, M.D.†

BOSTON

PATIENTS suffering from bleeding or protruding hemorrhoids can usually secure relief without operation. Since the Rectal Clinic was established at the Massachusetts General Hospital in 1928 the number of rectal operations has dropped markedly. Most of the patients are now treated in the clinic without loss of time and without taking up hospital beds.

Hayden<sup>1</sup> has described the treatment of internal hemorrhoids by injection, and Balch<sup>2</sup> has reviewed the results at the Massachusetts General Hospital for 1930-1932.

In the past two and a half years a series of 862 patients were seen in the Rectal Clinic of the Out Patient Department. There were 376 cases of hemorrhoids. Table 1 shows the relative frequency of the various conditions encountered in this large clinic. This paper is concerned only with a study of the 376 cases of hemorrhoids with especial reference to injection treatment.

# CLASSIFICATION

The anatomy of the anus as described in various books of anatomy needs no elaboration here. Hemorrhoids are divided into the external and internal varieties. External hemorrhoids are covered with skin, and are visible and sometimes palpable around the anal margin. These usually give no symptoms and cause very little inconvenience except for an occasional thrombosis or interference with anal hygiene. They should never be injected with sclerosing solutions. Due to the sensory nerve supply of the overlying skin and low vascularity, injection of external piles causes severe pain and usually necrosis.

Internal hemorrhoids are soft masses of varicose veins embedded in areolar tissue and covered with mucosa. They extend from the pectinate line upward into the rectum for about 3 cm. They vary in size, and in well-developed cases may become confluent, so that only two or three large piles are distinguishable. As the vessels dilate there is a tendency for the mucous membrane to become thin and granular, resembling a mulberry in appearance. These piles bleed on the slightest trauma.

TABLE 1 Diagnosis among 862 Consecutive Cases

DIAGNOSIS	NO OF CASES	DIAGNOSIS	NO OF CASES
Hemorrhoids	376	Polyp (adenomatous)	3
Pruritus	134	Polyp (squamous)	3
Anal fissure	179	Anal carcinoma	2
Anal fistula	57	Polypsosis	2

patients experienced no relief or had recurrence of symptoms and required subsequent treatment, either more injections or an operation. The injection treatment does not effect a radical cure but relieves the patient of symptoms and can be repeated as often as necessary. These figures are based on the assumption that patients who did not return were relieved of symptoms.

There was an abrupt decrease in the number of primary operations after the introduction of injection treatment. They decreased from 42 in 1929 to 5 in 1932. Since that time there has been a steady increase. This is due to the fact that we are now better able to judge the limitations of injection treatment.

#### TREATMENT OF EXTERNAL HEMORRHOIDS

There were 46 patients who had thrombosed external hemorrhoids. Half of these were operated on in the clinic. The rest were advised to take sitz baths and mineral oil, or required no treatment. Our policy in this condition is to operate

on the early painful cases. Under novocain an elliptical wedge of skin is removed from above the pile and the clot is shelled out. In patients who have mild symptoms and do not come in until the clot is several days old we either advise hot baths and mineral oil or give no treatment.

#### SUMMARY AND CONCLUSIONS

Three hundred and seventy-six cases of hemorrhoids are reviewed. Seventy-seven per cent of our cases of uncomplicated internal hemorrhoids were suitable for injection treatment. Of these, 81 per cent were completely relieved of symptoms for varying periods up to two years. The remainder experienced no relief or had recurrence of symptoms that required more injections or operation.

Injection treatment is simple and effective and is carried out as an ambulatory procedure.

## REPORT ON MEDICAL PROGRESS

### ENDOCRINOLOGY

JOSEPH C. AUB, M.D.\*

BOSTON

THE current literature concerning the glands of internal secretion is very large, and deals particularly with the physiological effects of the more recent, purified extracts. Much of this work is controversial and, therefore, difficult to evaluate. These preparations are largely derived from the gonads and from the anterior pituitary glands, and the extent of their clinical value is not yet completely clear. However, it is obvious that many of them are very potent.

When a drug has little pharmacological effect, its indiscriminate use is attended with little danger, but the converse is also true—the more effective the drug, the more discriminately must it be used. This is well exemplified in the purified hormones which are now available. It was not so long ago that simple dried gland preparations were the only ones obtainable. With the exception of the thyroid gland preparations, these exerted but a feeble influence. For instance, sometimes dried ovarian extract appeared to have an effect, though more frequently it seemed to

exert no obvious influence. Under these conditions, it made little difference whether the therapeutic indications for its use were correct or not. More potent endocrine drugs have now become available, and because of this, their use must be more carefully circumscribed. When an active preparation of the ovarian follicular hormone is used, it may have widespread effects: not only does it reduce the number of "hot flashes" for which it may have been prescribed, but it also has a stimulating effect on the uterus, the uterine endometrium and the breasts and a complicated inhibition of the functioning of the pituitary gland, all of which must be considered. The use of other hormones is complicated by just such widespread effects. Instead of simple, dried ovarian gland, one must now decide whether it is wiser to use the follicular hormone, the corpus luteum hormone or the sex-stimulating hormone of the anterior pituitary gland. All these have very different effects and, therefore, the indications for their use must be clear and distinct.

The more potent the drug, the more important

\*Associate professor of medicine, Harvard Medical School; physician in chief, Collis P. Huntington Memorial Hospital, Boston.

carried out until these have been corrected. Uncomplicated internal hemorrhoids are not as a rule palpable by digital examination.

A fenestrated anoscope, well covered with a greasy lubricant, is next introduced into the anus, and is pushed in as far as it will go before removing the obturator. This is necessary because in many cases the mucocutaneous line is deeply placed. This line can be readily identified by the alternating papillae and crypts about 2 or 3 cm from the anal margin. If an internal hemorrhoid is present in that quadrant, it will bulge into the window of the speculum.

The pile is wiped with a dry swab and cleaned with soap solution. Complete sterilization is impossible, and the use of iodine or other antiseptics is unnecessary. The danger of infection is negligible. We have not seen an abscess result, despite insufficient sterilization of the area of needle puncture. In the presence of known infection, injection should be postponed.

Using a 5-cc syringe filled with a solution of 5 per cent quinine and urea hydrochloride and fitted with a 26-gauge needle 4 cm long, the pile is punctured and 10 to 15 cc of the solution is injected directly into the center of the hemorrhoidal mass at a depth of 0.3 to 0.8 cm from the surface of the mucous membrane, according to the size of the pile. The needle puncture should be made 0.6 cm or more above the mucocutaneous line, and care should be taken not to inject either the submucous area, the outer wall of the bowel or the pararectal tissues. Submucous injection is likely to result in a slough, while injection into the bowel wall or pararectal tissue may produce a serious infection in the pelvis.

After the injection is completed, the obturator is replaced and the speculum removed. If necessary, this procedure is repeated until all four quadrants have been injected.

Most patients have a slight burning sensation following injection. This may last from thirty minutes to one hour. Very rarely patients experience actual pain. Injections are repeated at weekly intervals until the main symptoms of bleeding and protrusion disappear. In most cases bleeding stops and protrusion does not recur after the first injection, the treatment, however, should be carried out for three or four weeks unless palpable fibrosis or slough results. In this case only the piles not indurated should be injected. The patient is ambulatory during the treatment.

**Injection Treatment** Of the patients with internal hemorrhoids 77 per cent were advised to have injection and 18 per cent to have operation.

Two hundred and fifty-five of the patients received injection treatment for internal hemorrhoids. They received a total of 1119 injections. Some of the patients had only one injection, while others had more than twenty over a period of months. The average number per patient was four or five.

The number of injections into various quadrants is shown in Table 4. The left anterior quadrant

TABLE 4 *Quadrants Injected*

QUADRANT	NO. OF CASES
Right anterior	371
Right posterior	358
Left anterior	100
Left posterior	290
Total	1119

is much less frequently involved than the others. Our policy is to inject as many as three or four quadrants at the first visit, if necessary, and to repeat the treatment at intervals of one week. The hemorrhoids showing bleeding points or prolapsing are treated first.

Slough is the commonest complication of the injection treatment. It varies from a small area of mucous-membrane necrosis to complete destruction of the entire pile. Most of the sloughs in our cases consisted of small areas of necrosis unnoticed by the patient. They occurred twenty-four times in 1119 injections, an incidence of 2 per cent. Slough produces a sense of fullness and heat in the rectum, but very little pain unless it involves the epithelium of the anal canal, in which case pain is very severe. There is bloody discharge as the necrotic tissue liquefies, and healing gradually occurs in three to five weeks. Secondary hemorrhage is common but rarely serious. Ischiorectal abscess and fistula are spoken of as complications, but we have not encountered any in our cases. Pelvis phlebitis and pyemia are also described, but we have seen none. Furthermore, we have not observed either immediate or late untoward reactions from the injection of the quinine and urea hydrochloride solution.

**Surgical Treatment** There were 36 patients in the series who had hemorrhoidectomy, and 24 others who refused operation. Very large prolapsing or bleeding internal hemorrhoids, especially if they are accompanied by external ones, should be removed by operation. These cases will not be discussed, nor will those of 15 patients who had small hemorrhoids requiring no treatment.

**Results** Of the 255 patients who received injections for internal hemorrhoids 208, or 81 per cent, have been completely relieved of symptoms for varying periods up to two years. The remaining 47

dren below sixteen years of age whom they studied Rubinstein<sup>8</sup> also reported good results in stimulating hypoplastic genital development by the use of small doses of thyroid extract or, more effectively, by the use of either APL hormone or the anterior-pituitary sex hormone. This latter extract, of course, is substituting for the normal function of the anterior pituitary gland and is a way of stimulating the gonads to more active secretion. Evidence for this effect is found in the work of Sand and Plum,<sup>9</sup> who gave rather large doses of a Scandinavian preparation of APL hormone plus thyroid extract to children with dystrophia adiposogenitalis (Fröhlich's syndrome). Two out of 3 of the boys showed distinct increase in the urinary excretion of testosterone, and this was associated with a distinct clinical improvement. In children it is natural that increases in sex-hormone excretion should occur spontaneously, but these changes followed treatment so promptly that it appears highly likely that the stimulation came from the injected APL hormone. This gives an excellent physiological explanation of the matur-ing effect of gonadotropic hormones.

Kunstader<sup>10</sup> reports striking examples of premature puberty from the use of testosterone propionate (androsterone) in boys previously under-developed. The dose was only 5 mg., injected two or three times a week. This is obviously undesirable in children and indicates that the drug should not be used at this age. This is particularly true inasmuch as there is increasing evidence that its use inhibits the pituitary, which is such an important gland at puberty. Similar caution should be observed in the use of estrin preparations for infantile gonorrheal vaginitis, and this therapy should be temporarily discontinued if changes are noted in the breasts or genitalia.

The treatment of hypogonadism in the adult can be approached in two ways. The more desirable approach would be to stimulate the pituitary gland itself, thereby increasing its effect upon the gonads, but the technic for this is not as yet clear. A similar but sluggish effect can be obtained by potent anterior-pituitary gonadotropic hormones, but this technic has the disadvantage of somewhat inhibiting the patient's own pituitary gland. Synthetic testicular extract (testosterone) in injections up to 25 mg. three times a week increases the size and normal function of the accessory sex organs in a striking manner but some times has a temporarily inhibiting influence on the gonads themselves. It also appears to lessen the gonadotropic secretion of the pituitary gland.<sup>11</sup> However, the use of testosterone propionate produces a striking effect upon the eunuchoid habitus

in the male so that with caution it can be used therapeutically with success. Kenyon<sup>12</sup> gave testosterone propionate to four male eunuchoids in doses up to 25 mg. daily. The results were dramatic, with early increase in erections, enlargement of the penis and prostate, deepening of the voice, increase in sexual hair and marked increase in body weight. Vest and Howard<sup>13</sup> report the marked proportionate development of secondary sex organs, including the seminal vesicles and prostate, as well as the development of hair from the use of testosterone propionate. Their photographs demonstrate the striking changes they obtained. The amount of testosterone needed may be judged from the fact that from 7 to 21 mg. of testosterone must be metabolized daily in the normal man. This is arrived at from the amounts found in the urine.

Testosterone propionate also relieves the distressing menopausal symptoms of female castrates by intramuscular injection of about 10 mg. several times a week. Salmon,<sup>14</sup> Shorr and collaborators,<sup>15</sup> and more recently Birnberg, Kurzrok and Livingston<sup>16</sup> reported this and found the added advantage that it does not cause reactivation of the endometrium with its occasional return of menstrual bleeding.

Testosterone propionate has also been recommended in functional uterine bleeding. Inasmuch as it appears to suppress the ovarian function by depressing the anterior pituitary gland<sup>17</sup> it can be used to inhibit temporarily the menstrual cycle. Geist, Salmon and Gaines<sup>18</sup> report good results from this form of treatment in at least 18 of 25 cases. They used doses varying from 300 to 1000 mg. of testosterone propionate per month for several months. Within a month after treatment was stopped, endometrial biopsies disclosed normal ovarian secretion. All these effects of testosterone on both men and women have been confirmed by Dr. Nathanson in our laboratories.

The use of female sex hormones in the treatment of the menopausal syndrome has been well summarized recently by Hawkinson.<sup>19</sup> In 1000 consecutive patients, he obtained improvement in nearly 85 per cent. After about the eighth intramuscular injection of 10,000 international units of estrogen in oil or after two to three weeks of adequate oral treatment, many of the menopausal symptoms disappeared. It is to be expected that there would be a latent period before recovery.

Progesterone, the corpus-luteum hormone, has been used by Falls<sup>20</sup> and by Elden<sup>21</sup> in the treatment of habitual abortion. Falls has written a summarizing clinical paper, regarding the work of Falls, Krohn and Lackner, on the use of progesterone in obstetric complications. He speaks

is its dosage. This is obvious in the use of such extracts as are obtained from the thyroid gland, the parathyroid glands and the islands of Langerhans. Reliable objective and quantitative evidence can be obtained in regard to these by the determination of the basal metabolic rate, the blood calcium and the blood sugar, and so the dosage can be regulated. There is no such good objective evidence, however, to regulate the use of some of the other glandular preparations, and therapy must be controlled more empirically and, therefore, less efficiently, even though the preparation be effective.

The conclusion to be reached in regard to endocrine therapy seems obvious. The more effective the drug, the more we must know of its effects when used on human beings, and our physiological knowledge has certainly kept pace with our chemical improvements. The necessary knowledge is available, but the practical pharmacological application of these newly acquired facts cannot come so quickly. Let us remember that potent drugs can do harm as well as good, and let us be cautious in our use of these preparations.

It is also just as essential that the drug be indicated as that it be potent. Proper diagnoses are essential but in many cases difficult to make. It a menstrual disorder is dependent on a deficiency of corpus luteum, the giving of estrin will obviously not be therapeutically effective. The indiscriminate use of estrin, which is now common, proves little by its failures, for the crystalline preparations of this follicular hormone are potent if there is physiological need for them.

Up to the present, the least successful of purified hormones in clinical use has been the anterior pituitary hormone. The reasons for this are many. Its purification has been most difficult and depends not only on its animal source but also on the subsequent handling of the material,<sup>1</sup> for these extracts have not been brought to the high degree of purification which results in their crystallization or complete isolation. A second difficulty in regard to pituitary extracts is often the sluggishness of their action, for they have a far longer latent period than, for instance, has insulin. This is evident in the work of Nathanson<sup>2</sup> where it is demonstrated that the pituitary gland stimulates the production of sex hormones for many years before maturity occurs. It is obvious, therefore, that such stimulating drugs, even in large doses, will exert a slow therapeutic effect, for all the effects of the many anterior pituitary secretions seem to be the result of stimulating the other glands of internal secretion to proliferate and become active, and this secondary stimulation often appears slowly. A

third difficulty resulting from prolonged treatment with our present pituitary hormones (or with the anterior-pituitary-like [APL], sex stimulating hormone, which is probably made by the placenta) appears to be fatigue of the activated glands so that the stimulating effects wear off. Thus, an extract which needs prolonged use to produce changes, but which gradually loses its effectiveness, usually does not prove to be satisfactory. In spite of this, anterior pituitary extracts are giving evidence of some value in the treatment of growth retardation and in the stimulation of sex.

The treatment of undersized children by means of a potent growth hormone has been an outstanding need in medicine. For many years thyroid therapy has been used by the author because of the impression that it stimulated the pituitary gland. It appears to be mildly effective in stimulating growth, particularly in those children with a low basal metabolic rate and a marked retardation of "Bone-Age" development. There is also available a growth-promoting extract which is derived from the anterior pituitary gland. Such extracts, however, are very impure and are high in protein, and chemical purification has resulted in a low degree of potency, and it appears that several of the tropic pituitary hormones must be present in the extract in order to get the desired effect. Taylor<sup>3</sup> recently reported the effects of this therapy on 8 cases of retarded growth. In severe cases he obtained an increased increment of growth which indicated the value of the treatment. He used 2 cc of growth hormone three times a week (others have used larger doses). It must be emphasized that such growth hormone exerts its effects slowly and results should be judged over periods of many months or a year, not of weeks or days. Better results developed as the treatment continued, but startling rapidity of growth is not to be expected of this therapy at present.

The use of hormones for the treatment of undescended testicles in children has long been recommended. Recently, Thompson, Heckel, Thompson and Dickie<sup>4</sup> reported precocious puberty with marked hypertrophy of the genitalia from the use of large and prolonged doses of APL hormone. Hess and Kunstadter<sup>5</sup> did not observe such hypertrophy if they used more moderate doses, namely 100 to 200 rat units three times a week up to a total of 8000 units. Following the use of APL hormone for undescended testes in a seventeen-year-old boy, Powell<sup>6</sup> noted hypertrophy of the prostate, which apparently subsided after therapy was discontinued. Thompson, Heckel and Bevan<sup>7</sup> found with this preparation that testicular descent occurred in only about 33 per cent of the chil-

dren below sixteen years of age whom they studied Rubinstein<sup>8</sup> also reported good results in stimulating hypoplastic genital development by the use of small doses of thyroid extract or, more effectively, by the use of either APL hormone or the anterior-pituitary sex hormone. This latter extract, of course, is substituting for the normal function of the anterior pituitary gland and is a way of stimulating the gonads to more active secretion. Evidence for this effect is found in the work of Sand and Plum,<sup>9</sup> who gave rather large doses of a Scandinavian preparation of APL hormone plus thyroid extract to children with dysmorphia adiposogenitalis (Fröhllich's syndrome). Two out of 3 of the boys showed distinct increase in the urinary excretion of testosterone, and this was associated with a distinct clinical improvement. In children it is natural that increases in sex-hormone excretion should occur spontaneously, but these changes followed treatment so promptly that it appears highly likely that the stimulation came from the injected APL hormone. This gives an excellent physiological explanation of the maturational effect of gonadotropic hormones.

Kunstader<sup>10</sup> reports striking examples of premature puberty from the use of testosterone propionate (androsterone) in boys previously underdeveloped. The dose was only 5 mg, injected two or three times a week. This is obviously undesirable in children and indicates that the drug should not be used at this age. This is particularly true inasmuch as there is increasing evidence that its use inhibits the pituitary, which is such an important gland at puberty. Similar caution should be observed in the use of estrin preparations for infantile gonorrheal vaginitis, and this therapy should be temporarily discontinued if changes are noted in the breasts or genitalia.

The treatment of hypogonadism in the adult can be approached in two ways. The more desirable approach would be to stimulate the pituitary gland itself, thereby increasing its effect upon the gonads, but the technic for this is not as yet clear. A similar but sluggish effect can be obtained by potent anterior-pituitary gonadotropic hormones, but this technic has the disadvantage of somewhat inhibiting the patient's own pituitary gland. Synthetic testicular extract (testosterone) in injections up to 25 mg three times a week increases the size and normal function of the accessory sex organs in a striking manner but sometimes has a temporarily inhibiting influence on the gonads themselves. It also appears to lessen the gonadotropic secretion of the pituitary gland.<sup>11</sup> However, the use of testosterone propionate produces a striking effect upon the eunuchoid habitus

in the male so that with caution it can be used therapeutically with success. Kenyon<sup>12</sup> gave testosterone propionate to four male eunuchoids in doses up to 25 mg daily. The results were dramatic, with early increase in erections, enlargement of the penis and prostate, deepening of the voice, increase in sexual hair and marked increase in body weight. Vest and Howard<sup>13</sup> report the marked proportionate development of secondary sex organs, including the seminal vesicles and prostate, as well as the development of hair from the use of testosterone propionate. Their photographs demonstrate the striking changes they obtained. The amount of testosterone needed may be judged from the fact that from 7 to 21 mg of testosterone must be metabolized daily in the normal man. This is arrived at from the amounts found in the urine.

Testosterone propionate also relieves the distressing menopausal symptoms of female castrates by intramuscular injection of about 10 mg several times a week. Salmon,<sup>14</sup> Shorr and collaborators,<sup>15</sup> and more recently Birnberg, Kurzrok and Livingston<sup>16</sup> reported this and found the added advantage that it does not cause reactivation of the endometrium with its occasional return of menstrual bleeding.

Testosterone propionate has also been recommended in functional uterine bleeding. Inasmuch as it appears to suppress the ovarian function by depressing the anterior pituitary gland<sup>17</sup> it can be used to inhibit temporarily the menstrual cycle. Geist, Salmon and Gaines<sup>18</sup> report good results from this form of treatment in at least 18 of 25 cases. They used doses varying from 300 to 1000 mg of testosterone propionate per month for several months. Within a month after treatment was stopped, endometrial biopsies disclosed normal ovarian secretion. All these effects of testosterone on both men and women have been confirmed by Dr Nathanson in our laboratories.

The use of female sex hormones in the treatment of the menopausal syndrome has been well summarized recently by Hawkinson.<sup>19</sup> In 1000 consecutive patients, he obtained improvement in nearly 85 per cent. After about the eighth intramuscular injection of 10,000 international units of estrogen in oil or after two to three weeks of adequate oral treatment, many of the menopausal symptoms disappeared. It is to be expected that there would be a latent period before recovery.

Progesterone, the corpus-luteum hormone, has been used by Falls<sup>20</sup> and by Elden<sup>21</sup> in the treatment of habitual abortion. Falls has written a summarizing clinical paper, regarding the work of Falls, Krohn and Lackner, on the use of progesterone in obstetric complications. He speaks

enthusiastically about its use in threatened abortion. He has been using from 0.5 rabbit unit twice a week for prophylaxis up to 10 unit twice a day for patients with active symptoms. Elden's series of 6 successes in 8 cases is not sufficiently large to be convincing in a condition so prone to variations. However, the use of 10 to 45 international units of progesterone in his cases during the first six months of pregnancy is one with theoretical justification. Further data on this subject are needed.

Mortimer, Wright and Collip<sup>22</sup> have used estrogen (keto-hydroxyestrin or di-hydroxyestrin) in the treatment of atrophic rhinitis. The drug, dissolved in olive oil (100  $\mu$  gm per cc), is put in a nasal atomizer and about 0.25 cc is sprayed into each nostril at each application. Improvement is said to be obvious within a period of two to six weeks.

A good review of the pathologic physiology of the ovarian hormone has been written by Taylor,<sup>23</sup> in which the effects of the hormone on tissue growth are well summarized. This is a subject on which so much has been written recently that it seems wiser to refer those interested to Taylor's article rather than to review it here. The paper summarizes the more interesting, recent investigations concerning the therapeutic use of ovarian hormones. Such application is teaching us a great deal about their function and interrelations, and much is also being learned from the clinical syndromes which develop as a result of the overfunctioning of the ovaries themselves.

The tumors which produce abnormalities of sex may originate in one of several glands of which the ovaries and adrenals are most frequently involved. Since many of these tumors actively secrete their specific hormones, they give their most obvious effects when occurring in childhood, for they then produce early sexual maturity which may appear even before the age of one year. That they are always due to an increase in the normal hormone cannot be stated with too much assurance, since Broster and Vines<sup>24</sup> described the isolation of a new androgen in a case of virilism. This compound was found in a case of bilateral adrenal hyperplasia, and less of it was found after the removal of one adrenal gland. This suggests that it originated in the adrenal gland. The adrenal gland is certainly closely related to sex. It is unlikely that this function is present in cortin, the substance so important to the case of Addisonian adrenal insufficiency. The portion of the adrenal cortex which is said to be related to sex is the submucous layer, the so-called fuchsinophil (be-

cause of its staining reaction) layer. This is, however, a controversial point.

Two very good summaries of the relation of the adrenal gland to sex have recently been written by Young<sup>25</sup> and by Reilly, Lisser and Hinman.<sup>26</sup> Young found that abnormalities could originate from malignant or adenomatous tumors or from a bilateral hyperplasia of the adrenal cortex. Surgical intervention, therefore, requires the visualization of both adrenals to look for bilateral hyperplasia but particularly to determine that the involved adrenal is not the only one present. In childhood, the effects of adrenal cortical overactivity result in sexual precocity. In boys it produces rapid growth and the development of adult sized genitalia and of corresponding secondary sex characteristics. It must be noted, however, that in the single case we have seen the testicles were not so large as was to be expected from the marked secondary sexual maturity.

In girls and women the effects are usually masculinizing and are made evident by a shift of body configuration, hair distribution and breast development toward the masculine appearance. Amenorrhea is not unusual. The voice becomes deep, and there is an enlargement of the larynx. The most striking change is the enlargement of the clitoris, which may become the size of a small penis. In children the ovaries remain immature, though 1 out of 3 of Young's<sup>25</sup> cases, a five-year-old child, excreted 1200 rat units of estrogenic hormone per liter of urine, which is an extremely large amount. The gland from which this hormone originated is not clear. It must, however, be remembered that adrenocortical tumors are not always masculinizing in their effects, for Lisser<sup>27</sup> has recently reported that, in men, cortical tumors may also produce gynecomastia and feminization. But the usual effect is masculinizing.

A masculinizing tumor in women does not necessarily mean a tumor or hyperplasia of the adrenal cortex, for arrhenoblastomas of the ovaries will have a similar effect. Therefore, the differential diagnosis cannot be made from the general effects on the whole organism. Novak<sup>28</sup> has recently reviewed the literature on these ovarian tumors and has reported six new tumors which produced defeminization and masculinization phenomena. The striking masculinization effects again are hirsutism, deepening of the voice and hypertrophy of the clitoris, and with these usually go amenorrhea, regression of the mammary glands and loss of feminine contour. In 3 of his cases the tumors of the ovary proved to be primarily of adrenal tissue. Removal of the tumor is followed by a re-

turn toward normalcy. The manifestations of these tumors are no different from those of an adrenocortical tumor, so that every effort should be made to find which gland is overfunctioning, this frequently requires several operations. As one would expect, the masculinizing tumors of the ovary are less common than the feminizing tumors which arise in the same organ.

The sexual precocity which comes from a granulosa-cell tumor of the ovary is characterized by essentially normal sexual changes. When these changes appear at an early age, one then gets premature maturity. Inasmuch as this tumor secretes estrin, it produces adult female sex organs, with enlargement of the breasts and uterus and early menstruation. When it develops after the menopause, it produces a recurrence of uterine bleeding, endometrial hyperplasia and sometimes uterine polyps. The abnormal shift to masculine configuration that is seen in adrenal tumors or in arrhenoblastomas of the ovary is not found in patients with this lesion, for it is a feminizing tumor. It must also be recalled that similar general effects can be obtained through stimulation of the ovaries by an abnormally active anterior pituitary gland.

In this short report, the attempt has been made to summarize the recent advances in one phase of the endocrine field, namely the organs which influence sex development. This has been the field which has progressed most rapidly in the last few years because new active hormones have become available for therapeutic use and because new laboratory tests for studying the excretion of the hormones have been developed. Though much has been learned, it is to be expected that many further discoveries will develop.

enthusiastically, about its use in threatened abortion. He has been using from 0.5 rabbit unit twice a week for prophylaxis up to 1.0 unit twice a day for patients with active symptoms. Elden's series of 6 successes in 8 cases is not sufficiently large to be convincing in a condition so prone to variations. However, the use of 10 to 45 international units of progesterone in his cases during the first six months of pregnancy is one true theoretical justification. Further data on this subject are needed.

Marumet, Wright and Collip<sup>22</sup> have used estrogen (ketoandrosteron or dihydrosteron) in the treatment of atrophic rhinitis. The drug dissolved in olive oil (100  $\mu$  gm. per cc.), is put in a nasal atomizer and about 0.25 cc. is sprayed into each nostril at each application. Improvement is said to be obvious within a period of two to six weeks.

A good review of the pathologic physiology of the ovarian hormone has been written by Taylor,<sup>23</sup> in which the effects of the hormone on tissue growth are well summarized. This is a subject on which so much has been written recently that it seems wiser to refer those interested to Taylor's article rather than to review it here. The paper summarizes the more interesting, recent investigations concerning the therapeutic use of ovarian hormones. Such application is teaching us a great deal about their function and interrelations, and much is also being learned from the clinical syndromes which develop as a result of the over-functioning of the ovaries themselves.

The tumors which produce abnormalities of sex may originate in one of several glands of which the ovaries and adrenals are most frequently involved. Since many of these tumors actively secrete their specific hormones, they give their most obvious effects when occurring in childhood, for they then produce early sexual maturity which may appear even before the age of one year. That they are always due to an increase in the normal hormone cannot be stated with too much assurance, since Broster and Vines<sup>24</sup> described the isolation of a new androgen in a case of virilism. This compound was found in a case of bilateral adrenal hyperplasia, and less of it was found after the removal of one adrenal gland. This suggests that it originated in the adrenal gland. The adrenal gland is certainly closely related to sex. It is unlikely that this function is present in cornu, the substance so important to the case of Addisonian adrenal insufficiency. The portion of the adrenal cortex which is said to be related to sex is the submucous layer, the so-called fuscinophil (be-

cause of its staining reaction) layer. This is, however, a controversial point.

Two very good summaries of the relation of the adrenal gland to sex have recently been written by Young<sup>25</sup> and by Reilly, Lasser and Hinman.<sup>26</sup> Young found that abnormalities could originate from malignant or adenomatous tumors or from a bilateral hyperplasia of the adrenal cortex. Surgical intervention, therefore, requires the visualization of both adrenals to look for bilateral hyperplasia but particularly to determine that the involved adrenal is not the only one present. In childhood, the effects of adrenal cortical overactivity result in sexual precocity. In boys it produces rapid growth and the development of adult-sized genitalia and of corresponding secondary sex characteristics. It must be noted, however, that in the single case we have seen the testicles were not so large as was to be expected from the marked secondary sexual maturity.

In girls and women the effects are usually masculinizing and are made evident by a shift of body configuration, hair distribution and breast development toward the masculine appearance. Amenorrhea is not unusual. The voice becomes deep, and there is an enlargement of the larynx. The most striking change is the enlargement of the clitoris, which may become the size of a small penis. In children the ovaries remain immature, though 1 out of 3 of Young's<sup>25</sup> cases, a five-year-old child, excreted 1200 rat units of estrogenic hormone per liter of urine, which is an extremely large amount. The gland from which this hormone originated is not clear. It must, however, be remembered that adrenocortical tumors are not always masculinizing in their effects, for Lasser<sup>27</sup> has recently reported that, in men, cortical tumors may also produce gynecomastia and feminization. But the usual effect is masculinizing.

A masculinizing tumor in women does not necessarily mean a tumor or hyperplasia of the adrenal cortex, for arrhenoblastomas of the ovaries will have a similar effect. Therefore, the differential diagnosis cannot be made from the general effects on the whole organism. Novak<sup>28</sup> has recently reviewed the literature on these ovarian tumors and has reported six new tumors which produced defeminization and masculinization phenomena. The striking masculinization effects again are hirsutism, deepening of the voice and hypertrophy of the clitoris, and with these usually go amenorrhea, regression of the mammary glands and loss of feminine contour. In 3 of his cases the tumors of the ovary proved to be primarily of adrenal tissue. Removal of the tumor is followed by a re-

and did fairly until about one month before entry, when she again became nervous and weak and had general malaise.

Physical examination showed a well-developed and nourished woman in moderate distress from asthma. She was excited, crying and weak. The face showed a dozen scattered reddish papules. The legs were swollen, and there were many papulopustular lesions over the legs and ankles. There were musical rales in the chest. Examination of the heart was negative. The blood pressure was 150 systolic, 90 diastolic. The reflexes were normal, but the hands showed slight tremor.

The temperature was 97.6°F, the pulse 95, and the respirations 23.

The urine showed a trace of albumin, and the sediment contained 5 white cells, with a rare small clump, per high-power field. A phenolsulfonephthalein kidney-function test showed no impairment. The blood showed a red-cell count of 4,200,000 with 75 per cent hemoglobin, and a white-cell count of 10,100 with 56 per cent polymorphonuclears, 3 per cent large lymphocytes, 24 per cent small lymphocytes, 4 per cent mononuclears and 13 per cent eosinophils. A blood Hinton test was negative. The nonprotein nitrogen of the serum was 19 mg per 100 cc. The sedimentation rate was 22 mm in fifteen minutes, 48 mm in thirty minutes, 54 mm in forty-five minutes, 58 mm in sixty minutes. Two blood cultures were negative. Sputum examinations showed no acid-fast bacilli. A urine culture showed non-hemolytic streptococci.

X-ray films of the chest showed a marked change in the heart shadow since the last examination. The heart was diffusely enlarged. The pulsations were rapid and weak. The lung fields remained the same.

On the fifth hospital day the patient had a severe asthmatic attack which was relieved promptly by 4 gr of aminophyllin intravenously. On the twelfth hospital day a portable chest film was taken which showed the heart shadow to be apparently somewhat smaller than previously. The lung fields were less radiant. Two days later an electrocardiogram showed a regular rate of 120. The P-R interval was 0.16 sec. T<sub>1</sub> and T<sub>4</sub> were low, T<sub>2</sub> and T<sub>3</sub> inverted. An x-ray film of the chest on the twenty-sixth hospital day showed a small amount of fluid at the left base. On the thirty-sixth hospital day there was bronchial breathing in the left base. Since entry her chart had been essentially normal except for a rapid pulse rate varying between 90 and 140. A blood examination on the thirty-sixth day showed a red-cell count of 4,200,000 and a white-cell count of 15,000 with 43 per cent polymorphonuclears, 1

per cent large lymphocytes, 2 per cent small lymphocytes, 1 per cent mononuclears, 43 per cent eosinophils and 1 per cent basophils. Physical examination at this time revealed red skin lesions on each cheek and it was noted that she had had similar lesions on her nose. There were also alternate pale and heavily pigmented areas on the forehead. No heart murmurs were heard, and there was no pericardial friction rub. The heart beat was regular at 150, with gallop rhythm heard at the apex and lower left border of the sternum.

On the thirty-eighth hospital day a pleural friction rub was heard over a wide area to the right of the sternum, extending to the right anterior axillary line. Moist crackling rales were heard toward each side and in each axilla. The following day there was dullness over both bases, extending to the angles of the scapulae. The patient was very weak and stated that she was going to die. The pulse remained at 160. The respirations increased to 35. Another blood count showed 17,700 white cells with 47 per cent polymorphonuclears, 1 per cent large lymphocytes, 13 per cent small lymphocytes, 7 per cent mononuclears and 32 per cent eosinophils. She rapidly failed, and died on the forty-second hospital day.

#### DIFFERENTIAL DIAGNOSIS

DR. J. H. MEANS. This is a long and complicated story dividing itself into several chapters which may or may not be importantly related. I think it may simplify matters if I pick one item as a sort of text for my talk, namely the eosinophilia, which is very impressive. An eosinophilia of these proportions is not a particularly common laboratory finding, but there are so many counts here that we can assume that this finding is correct and that we are truly dealing with marked eosinophilia, at first with a normal total white count and later moderate leukocytosis. Furthermore, this eosinophilia became progressively greater as time went on.

There are only a few diseases in these parts that will produce an eosinophilia of this degree. One is, of course, trichinosis and one is, perhaps, asthma, which she had, so we are told, and the third, periarteritis nodosa. Eosinophilia occurs in asthma, but yesterday, without asking anything else about the case,—I did not request help but information stated in an abstract way,—I asked Dr. Rackemann how high an eosinophilia one can get in uncomplicated asthma. He did not like the term 'uncomplicated asthma,' and he did not want to state a figure, and he can contradict me now it I am interpreting him incorrectly, but I got the impression that he thought it unsafe to attribute an eosinophilia as high as 40 per cent to uncon-

### CASE 25141

#### PRESENTATION OF CASE

*First Admission* A thirty-seven-year-old single, female, Hebrew bookkeeper was admitted with a diagnosis of left renal colic.

Three years prior to admission she had had two attacks of pain, the first in the left abdomen, the second in the left back. X-ray films and intravenous pyelograms were negative. She knew of no hematuria at that time. Nine months before entry she had had a cholecystectomy for chronic cholecystitis. The uterus was also removed because of a "growth." Following this she had a right pyelitis. Pus, blood and bacteria were found in the urine. In spite of treatment she continued having malaise and abdominal pain, not localized to any one point. "Indigestion" had remained the same as it was previous to her gall-bladder operation. A few weeks before entry an x-ray diagnosis of left-sided kidney stone was made at an outside hospital. During the previous two weeks she had had a chronic upper respiratory infection. Her tonsils had been removed and her sinuses drained in childhood. Ten years before entry an appendectomy was done. Her catamenia had been regular and normal up to the time of hysterectomy.

Physical examination definitely showed more tenderness in the right costovertebral angle than in the left. The remainder of the physical examination was essentially negative. The blood pressure was 135 systolic, 80 diastolic. The urine examination was negative except for the presence in the sediment of 2 white cells and numerous bacteria per high-power field. The blood showed a red-cell count of 4,670,000 with 80 per cent hemoglobin, and a white-cell count of 11,900 with 70 per cent polymorphonuclears, 1 per cent large lymphocytes, 19 per cent small lymphocytes, 6 per cent mononuclears and 4 per cent eosinophils, the platelets were slightly increased.

On the fifth hospital day a left ureteral calculus was removed, and she was discharged on the twenty-second hospital day.

*Second Admission* (twenty-one months later) One year and a half before re-entry she developed asthmatic symptoms, and six months later began to have marked blocking of the nose, sneezing and

watery discharge. Physical examination revealed edematous polypoid tissue in the region of the middle meatus on each side of the nose. X-ray films showed distinct cloudiness of both antrums. Examination of the urine was negative. The blood showed a red-cell count of 3,900,000 with 65 per cent hemoglobin, and a white-cell count of 15,100 with 57 per cent polymorphonuclears, 22 per cent small lymphocytes, 3 per cent mononuclears and 17 per cent eosinophils. On the second hospital day a bilateral radical antrum operation, including bilateral ethmoidectomy and sphenoidectomy, was done. Her chart remained essentially normal. She was discharged on the fifteenth hospital day.

*Third Admission* (two months later) Following her antrum operation the patient noticed no improvement. The nose remained obstructed and she breathed through the mouth. There was swelling of the face over the antrums, and swelling of the lower lid on the left and upper lid on the right, which caused some interference with vision. Her symptoms had increased during the previous three weeks. About one month before admission she was ill with pain in the right lower chest, which was aggravated by deep breathing. She also suffered from generalized body aches, especially in the knees and shoulders. She did not have fever. Physical examination showed markedly infected sinuses with what proved to be a pure culture of *Staphylococcus aureus*. She had diplopia which increased in looking down to the right. There was paresis of the right superior oblique muscle. The visual fields were normal. The remainder of the physical examination was negative. The blood pressure was 120 systolic, 80 diastolic. The temperature was 100°F, the pulse 90, and the respirations 16. Examination of the urine was negative. The blood showed a red cell count of 4,640,000 with 80 per cent hemoglobin, and a white-cell count of 19,800 with 53 per cent polymorphonuclears, 1 per cent large lymphocytes, 15 per cent small lymphocytes, 6 per cent mononuclears, 24 per cent eosinophils and 1 per cent basophils. The serum protein was 6.8 gm per 100 cc. X-ray films of the chest showed thickening of the apical pleura on both sides. The lung fields were otherwise clear. The diaphragm was low in position but moved well with respiration on both sides. The heart shadow was not remarkable. The patient was discharged on the fifth hospital day.

*Final Admission* (seven months later) Two months before her final admission she was told that she had an "upset thyroid" at an outside hospital, where she remained for three weeks. The basal metabolism rate fell from +40 to +16 per cent. Following this she returned to work

them, I can assume they cleared up. I can think of one thing that could produce this picture, namely an iodine rash. On this admission the asthma became worse, and another interesting feature is that her heart rapidly became larger. The cardiographic evidence shows no interference with the conduction system but does show evidence of some myocardial disease, with a rapid, weak pulse, with a rapidly enlarging heart which later became smaller and with gallop rhythm. All this indicates to me that she had very extensive and grave myocardial disease at that time. She may also have had a pericardial effusion, there are no data that permit me to state that definitely, but the fact that the heart got larger and then smaller makes one wonder if she had accumulated some fluid and then reabsorbed a portion of it. I cannot go farther with that, it is just a possibility. She had evidence of a process in both pleurae, with fluid on the left. There was some kind of parenchymatous disease in the lungs, whether it was pneumonia or infarct or something else, I am not capable of saying with the information at hand. Then she became rapidly sicker and died, not of asthma apparently, according to the story, but with a steadily mounting white count and relatively high eosinophilia.

I state that this patient had periarthritis nodosa because I do not see how, with the data provided, one can make any other diagnosis. If one can, I shall learn a great deal. I think that disease was the chief cause of her death. I know that the disease kills almost invariably in short order, but I gather that the course may be longer than the textbooks state it to be, which is only a few months. I believe that she also had asthma, and I should suggest, although this is largely Dr Rackemann's idea, that there is some association between asthma and periarthritis nodosa.

Another thought that occurs to me is that, since she had a queer skin lesion on her face and had involvement of many serous surfaces and her heart, she may have had lupus erythematosus disseminatus. I recall that Dr Soma Weiss standing on this very spot, or near it, a year or two ago made a diagnosis of lupus erythematosus disseminatus and Dr Mallory made a diagnosis, on the same patient, of periarthritis nodosa. That would suggest that there is a relation between periarthritis nodosa and lupus erythematosus disseminatus. They are both diseases which involve blood vessels, periarthritis involving middle-sized arteries supplying muscles, and lupus involving much smaller arteries near the surface and giving serous involvement. Either may have myocardial and renal complications. I wonder if they may not be the same disease. Perhaps in one case the involve-

ment is chiefly of somewhat larger arteries and in another of smaller arteries or sometimes of both. I am going to throw in lupus as a good possibility, and assume that the lupus, if she had it, and the periarthritis, which I am sure she had, either jointly or singly involved the myocardium extensively. My diagnosis reads periarthritis nodosa, asthma, and possibly lupus erythematosus disseminatus. She had a low-grade infection of the urinary tract, perhaps with some stones remaining. She had a chronic pansinusitis. I do not believe she had a brain abscess. The heart, as I see it, was parenchymatously involved. There was no valve lesion, no endocarditis. She may have had pericarditis. She had bilateral pleurisy, old and new, with effusion on the left. She had something going on in the lungs, whether it was pneumonia or infarct or consolidation that was directly due to the periarthritis nodosa, I do not know.

DR FRANCIS M RACKEMANN. There is a tremendous difference between looking at the patient on the one hand and reading this account on the other. I marvel at the way Dr Means can throw away the irrelevant parts of this history and bring out the other parts which are so important. Meantime the history is hardly fair, because there were one or two things that would have helped Dr Means considerably. When this woman came to the hospital for the last admission, skin lesions were apparent on her face but they did not amount to much. They were small reddish papules with some superficial scaling, diffusely scattered on both sides of the forehead and with one or two over the malar eminences. There was nothing remarkable about them,—no butterfly appearance,—and in my mind they passed off as an iodine rash. She had the same thing on the ankles, but there were only a very few lesions, and they were, on the whole, unimportant. Last night in going over my record more carefully I recalled another skin lesion not thought of at the time and not mentioned here. Over the inner malleolus on the left side there was a round, swollen, purplish area about 5 cm in diameter, which I presume was an early lesion of periarthritis. Also not mentioned in the history was the fact that she had had one hemoptysis, which seemed to us of some importance.

On the second hospital day of the last admission a pleurisy developed. The friction rub was perfectly obvious. The pleurisy came rather early in the disease, and it continued throughout her stay, with evidence of increasing fluid in both chests. On account of this pleurisy, this serositis, most of the doctors who saw her thought first of lupus erythematosus, with periarthritis as a secondary consideration. From the clinical point of view

plicated asthma I do not believe she had trichinosis.

Now we can proceed. Let us take up admission by admission and see what we can make out of each. It is obvious on the first one that she had urinary lithiasis. They took out a stone and found that she had infection of the urinary tract. The stone came from the left and the tenderness was more marked on the right, so we are entitled to believe she had bilateral infection, at least of the pelves of the kidneys. We take note of the fact that this woman had been simplified by the removal of various organs. The gall bladder had been taken out, this did not relieve the symptoms, so I assume she did not have gall-bladder disease that was causing symptoms. Why they took out the uterus we are not told. It is to be noted also that she had in the past had her appendix removed. Lastly she had this operation in which they took out the calculus, after which she was discharged, this permits us to assume that she was relieved of the immediate difficulty.

Twenty-one months later we learn that she developed asthma or something that resembled it and led to that diagnosis. We also learn she had a troublesome rhinitis with polyps, also infection of the antrums. I suspect that she had infection of all her accessory sinuses with polyps. We know that asthma is very frequently associated with nasal polyps and sinus infection so that it is not surprising to find these conditions associated here, and one might suspect that the nasal infection and sinus infection had something to do with the asthma. I think it is perfectly reasonable to suppose she suffered from intrinsic asthma that had to do with this chronic upper respiratory infection. It is interesting to know that at that time her eosinophilia began, and it might well have been due to asthma. Then she had a radical sinus operation which apparently did her no good. I suspect it did her harm, but I cannot prove it.

On the third admission she had a suppurative pansinusitis. In addition, there was a picture of acute pleurisy at the right base, with thickening of both pleurae at the apices, according to the x-ray film, so at this time we have evidence of acute and chronic pleural disease involving both sides. Then she had this interesting swelling of the eyelids, also some swelling over the antrums. I suspect these may have been due to the sinus infection, although I cannot prove it. She may have had angioneurotic edema for all I know. But in trying to put things together I believe that this swelling in some way had something to do with the widespread suppurative affair in the sinuses, many of which had been denuded of the mucous membrane

surgically. We learn later that she was thought to have had some disease of the thyroid, and of course one gets puffiness of the eyelids in Graves's disease, but I cannot reconcile this description with the puffiness seen in exophthalmic goiter. One also gets puffiness of the eyes in trichinosis, which also has increased eosinophilia, but that does not seem to fit the picture in this case. I think the swelling probably had to do with the local infection. She also had a palsy of the left superior oblique muscle, causing diplopia. By consulting a textbook of anatomy, I discovered that that muscle is innervated by the fourth cranial nerve and that nerve runs along in close proximity to the orbit on its mesial surface, so it is not far away from the infected sinuses. Of course with all her sinus infection she might have had a brain abscess, and that might have affected this one nerve. I believe if it was in the posterior fossa it could do so. I looked up also in a textbook of neurology the causes of palsy of the fourth nerve. It made no mention of peripheral factors. I also waylaid Dr. Ayer in the corridor and said, "Do not help me any but answer this question, Can sinusitis give a palsy of the fourth nerve?" He thought awhile and said that he had never seen it but that it probably could. So I am going to cling to that explanation because I do not believe she had a brain abscess. I do not believe so because we do not hear any more about it and she lived for some time without developing any other neurological symptoms. Furthermore, I am going to blame the sinus infection for the swelling of the eyelids. I am interested that she had a normal heart at this time and that the eosinophilia was greater than that on the previous entry.

On the next entry we hear that she had an "upset thyroid." One cannot possibly make a diagnosis of thyroid disease on the information we have. I shall say that if she did have toxic goiter, —and she may have had it,—it is interesting to note that the basal metabolic rate came down from +40 to +16 per cent. It might do that from natural causes or because someone gave iodine. Whether someone did, we do not know, but at any rate she got better.

On her final admission the only things that suggest thyrotoxicosis are a slight tremor and a tachycardia. At this time she had a remarkable series of significant lesions. Her legs were described as swollen, and there were many pustular lesions over the legs and ankles, on her face there were scattered reddish papules. I should really like to know how they were scattered, whether they were symmetrically arranged in butterfly patterns, but we are not told. I do not know what these lesions were, as no further mention is made of

them, I can assume they cleared up. I can think of one thing that could produce this picture, namely an iodine rash. On this admission the asthma became worse, and another interesting feature is that her heart rapidly became larger. The cardiographic evidence shows no interference with the conduction system but does show evidence of some myocardial disease, with a rapid, weak pulse, with a rapidly enlarging heart which later became smaller and with gallop rhythm. All this indicates to me that she had very extensive and grave myocardial disease at that time. She may also have had a pericardial effusion, there are no data that permit me to state that definitely, but the fact that the heart got larger and then smaller makes one wonder if she had accumulated some fluid and then reabsorbed a portion of it. I cannot go farther with that, it is just a possibility. She had evidence of a process in both pleurae, with fluid on the left. There was some kind of parenchymatous disease in the lungs, whether it was pneumonia or infarct or something else, I am not capable of saying with the information at hand. Then she became rapidly sicker and died, not of asthma apparently, according to the story, but with a steadily mounting white count and relatively high eosinophilia.

I state that this patient had periarteritis nodosa because I do not see how, with the data provided one can make any other diagnosis. If one can, I shall learn a great deal. I think that disease was the chief cause of her death. I know that the disease kills almost invariably in short order, but I gather that the course may be longer than the textbooks state it to be, which is only a few months. I believe that she also had asthma, and I should suggest, although this is largely Dr. Rackemann's idea, that there is some association between asthma and periarteritis nodosa.

Another thought that occurs to me is that, since she had a queer skin lesion on her face and had involvement of many serous surfaces and her heart, she may have had lupus erythematosus disseminatus. I recall that Dr. Soma Weiss standing on this very spot, or near it, a year or two ago made a diagnosis of lupus erythematosus disseminatus and Dr. Mallory made a diagnosis, on the same patient, of periarteritis nodosa. That would suggest that there is a relation between periarteritis nodosa and lupus erythematosus disseminatus. They are both diseases which involve blood vessels, periarteritis involving middle-sized arteries supplying muscles, and lupus involving much smaller arteries near the surface and giving serous involvement. Either may have myocardial and renal complications. I wonder if they may not be the same disease. Perhaps in one case the involve-

ment is chiefly of somewhat larger arteries and in another of smaller arteries or sometimes of both. I am going to throw in lupus as a good possibility, and assume that the lupus, if she had it, and the periarteritis, which I am sure she had, either jointly or singly involved the myocardium extensively. My diagnosis reads periarteritis nodosa, asthma, and possibly lupus erythematosus disseminatus. She had a low-grade infection of the urinary tract, perhaps with some stones remaining. She had a chronic pansinusitis. I do not believe she had a brain abscess. The heart, as I see it, was parenchymatously involved. There was no valve lesion, no endocarditis. She may have had pericarditis. She had bilateral pleurisy, old and new, with effusion on the left. She had something going on in the lungs, whether it was pneumonia or infarct or consolidation that was directly due to the periarteritis nodosa, I do not know.

DR. FRANCIS M. RACKEMANN. There is a tremendous difference between looking at the patient on the one hand and reading this account on the other. I marvel at the way Dr. Means can throw away the irrelevant parts of this history and bring out the other parts which are so important. Meantime the history is hardly fair, because there were one or two things that would have helped Dr. Means considerably. When this woman came to the hospital for the last admission, skin lesions were apparent on her face but they did not amount to much. They were small reddish papules with some superficial scaling, diffusely scattered on both sides of the forehead and with one or two over the malar eminences. There was nothing remarkable about them,—no butterfly appearance,—and in my mind they passed off as an iodine rash. She had the same thing on the ankles, but there were only a very few lesions, and they were, on the whole, unimportant. Last night in going over my record more carefully I recalled another skin lesion not thought of at the time and not mentioned here. Over the inner malleolus on the left side there was a round, swollen, purplish area about 5 cm. in diameter, which I presume was an early lesion of periarteritis. Also not mentioned in the history was the fact that she had had one hemoptysis, which seemed to us of some importance.

On the second hospital day of the last admission a pleurisy developed. The friction rub was perfectly obvious. The pleurisy came rather early in the disease, and it continued throughout her stay, with evidence of increasing fluid in both chests. On account of this pleurisy, this serositis, most of the doctors who saw her thought first of lupus erythematosus, with periarteritis as a secondary consideration. From the clinical point of view

the striking feature was the sudden change which came over this rather healthy, bright and cheerful woman who came to the hospital in fair condition. She had chronic vasomotor rhinitis, chronic sinus disease and some asthma. Then she proceeded to go downhill. Fortunately there had been an x-ray film taken not so long before the admission, and when the new x-ray film was taken, the change in the heart size was seen to be extraordinary.

If I may have a moment, I should like to say that in going over a series of 900 patients with asthma I find 32 cases in which a story of chronic vasomotor rhinitis had preceded the asthma by two or three years. These patients evidently developed the rhinitis first and then had asthma of severe type beginning suddenly in the midst of chronic vasomotor rhinitis. All of them had sinus disease at the time. That is a very small group, only 32 out of about 900, but 10 of them have died, so that this disease which begins with a vasomotor rhinitis and goes on to asthma of a severe type is evidently a serious one. It should be said, however, that at least 3 of the group are now cured, being free of symptoms and signs at the present time. The symptom complex does not necessarily imply a fatal outcome. I believe, as Dr. Means suggested, that the sinus disease is in no way a cause of the trouble but that the sinus disease and the asthma together are part of a symptom complex which we can call "intrinsic asthma." The nature of it we know nothing about.

#### CLINICAL DIAGNOSIS

Periarthritis nodosa

#### DR. MEANS'S DIAGNOSES

Periarthritis nodosa (chief cause of death)  
Bronchial asthma  
Lupus erythematosus disseminatus?  
Diffuse myocarditis  
Pericarditis with effusion?  
Old and new pleurisy, with effusion on left  
Parenchymatous lung lesion, type uncertain  
Suppurative pansinusitis  
Chronic urinary tract infection

#### ANATOMICAL DIAGNOSES

Periarthritis nodosa  
Pericarditis with effusion  
Chronic degenerative myocarditis, focal  
Hydrothorax, bilateral  
Pulmonary atelectasis, bilateral  
Dermatitis, papulo-pustular (? iodine rash)  
Operative scars: appendectomy, cholecystectomy, ureterotomy

#### PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: The autopsy of this patient showed a pericarditis with a considerable accumulation of turbid, almost purulent, fluid and bilateral pleural effusions with relatively clear fluid. The heart itself was a little but not strikingly enlarged. When it was cut, obvious spots of gross discoloration in the myocardium enabled one to make grossly a diagnosis of myocardial degeneration. There was no endocarditis. The lungs were rather diffusely collapsed. There were no signs of asthma, but there were one or two small foci of consolidation. The kidneys were a little large, about 400 gm., but there was no evidence of any persisting infection in the renal pelvis or elsewhere in the urinary tract. On microscopical examination, arteries were found in various organs, particularly in the myocardium, which were sufficiently characteristic to enable one to make a definite diagnosis of periarteritis nodosa. There was also an extensive nephritis of a focal glomerular type. We did not happen to catch any arterial lesions in the kidney. The liver showed a very severe central necrosis. One pulmonary artery showed a lesion which was very suggestive of periarteritis nodosa. This is the first time I have seen a lesion in a pulmonary artery, though we have seen them in the bronchial arteries. From the anatomical point of view there is no possible question of the diagnosis. Dr. Means's suggestion that she had lupus erythematosus disseminatus is a safe one because I cannot rule it out on an anatomical basis. However, I cannot restrain myself from expressing a clinical opinion and saying that I do not believe she had it.

DR. RACKEMANN: Did her kidneys show wire loop lesions?

DR. MALLORY: No, but only 1 of 16 cases of lupus erythematosus that we have carefully studied has shown that lesion.

DR. MEANS: Was anything wrong with the thyroid gland?

DR. MALLORY: No.

DR. MEANS: Was the brain examined?

DR. MALLORY: Yes, grossly. There certainly was no abscess.

#### CASE 25142

#### PRESENTATION OF CASE

A thirty-eight-year-old white married woman was admitted complaining of diarrhea.

Since the age of six years the patient had more or less regularly had diarrhea with six to eight movements in twenty-four hours, occasionally at night. Blood-streaking was present at the onset

Two years of regulated life in a boarding school gave her one or two normal bowel movements a day and she was distinctly better during her first year and a half in college. Nineteen years prior to admission the diarrhea became very much worse and was associated with a considerable amount of bleeding. At the age of twenty-five years an acutely inflamed appendix was removed. At operation it was noted that the terminal 45 cm of the ileum was thickened and surrounded by slightly enlarged lymph nodes, the sigmoid and cecum were considerably thickened, the transverse colon only slightly. In the same year she was treated for fistula and fissure in ano. The diarrhea continued with six to eight movements a day.

Because of profuse painful catamenia a bilateral oöphorectomy was done when she was thirty-one years of age. The pathological diagnosis was endometriosis. The ileum was found to be very much dilated and thickened, and the cecum had contracted to the size of the ileum. The colon everywhere was much thickened and narrowed. She stated that prior to this operation her menses had always increased the bowel activity and discomfort.

During the next seven years her condition remained essentially unchanged. Numerous stool examinations for parasites were negative. Her weight remained at about 130 pounds. From time to time the anal sphincter was dilated.

Physical examination showed a well-developed and nourished woman who appeared much older than her stated age. The skin was drawn tight, wrinkled and dry. There was no abnormal pigmentation. The nails were brittle. The thyroid gland was not palpable, and there was no tremor. Examination of the chest was negative. The blood pressure was 120 systolic, 80 diastolic. The abdomen was soft. There was a definite, rounded, tender mass in the right upper quadrant in relation to the distal portion of the proximal half of the transverse colon. It seemed to move down slightly with respiration. By rectal examination the mucocutaneous region was pale and slightly thickened. The anal ring was narrowed, inelastic and roughened. Five centimeters above the sphincter there was a second narrowing, more contracted than the first, and introduction of the fingertip caused slight discomfort to the patient.

The temperature was 99.5°F, the pulse 80, and the respirations 18.

Examination of the urine was negative. The blood showed a red-cell count of 5,240,000 with 85 per cent hemoglobin, and a white-cell count of 19,300 with 80 per cent polymorphonuclears, 17 per cent lymphocytes and 3 per cent eosinophils.

The platelets were normal. The nonprotein nitrogen of the serum was 17 mg per 100 cc. A stool examination was guaiac positive.

A gastrointestinal x-ray series was negative. A barium enema showed the entire colon to be abnormal. The rectum did not dilate to the usual size, and the walls of the sigmoid and descending colon were more or less rigid with irregular wavy outlines. There was definite obstruction to the flow of barium at about the middle of the transverse colon. After considerable delay, small amounts passed through this portion of the transverse colon, between the midline and the hepatic flexure was a constriction with a ragged, mottled outline. No normal mucosa could be demonstrated in this area. The patient evacuated the enema satisfactorily, and there did not appear to be any definite obstruction to the flow of intestinal contents in the normal direction. After six weeks, during which time the patient complained of some soreness in the region of the mass, the barium enema was repeated. It met a complete obstruction at the midportion of the transverse colon, and only a trace of barium passed beyond this point to the hepatic flexure. The lumen of this portion was reduced to a very narrow channel and the mucosa was completely destroyed. The distal margins of a mass in the wall of the bowel were demonstrated. The mucosa throughout the distal colon was also destroyed, the haustral markings being absent. The cecum and ascending colon could be examined only from six-hour barium-meal films, both showed acute ulceration. Nine days later an ileostomy was done. Four months later another abdominal operation was performed.

#### X-RAY INTERPRETATION

DR. GEORGE W. HOLMES: I can only point out some of the things that have been stated in the notes. This is the point of obstruction at the time of the last observation. This is the posterior portion of the bowel, which is dilated. It has a peculiar mucosal pattern in the first portion, but it is apparently not very rigid. In the early examination this point beyond the stricture is also abnormal so far as the mucosa is concerned.

DR. HORATIO ROGERS: How about the mass demonstrated as a tumor in the wall of the bowel?

DR. HOLMES: There is an area here close to the stricture. But it does not look like a tumor mass in this film. I do not believe there was a tumor.

DR. ROGERS: How much change took place between the first examination and the second, six weeks later, with regard to that area?

DR. HOLMES: A change from partial obstruction to complete obstruction, whether it is organic,

I am not certain It could be due to spasm the second time An ulcerated area which was active one time and not the next might do it I do not believe we have enough evidence to say that there is a new growth which has increased in size, but I think from Dr Lingley's report that that is what he had in mind This film certainly does look very much like a tumor mass This lobulated effect looks decidedly like tumor A little later I should say that same area does not look that way at all

#### DIFFERENTIAL DIAGNOSIS

DR ROGERS We can summarize this case as one of diarrhea and bleeding of thirty-two years' duration, with remissions and exacerbations Sixteen years after the onset a surgeon operated on her and found a picture consistent with regional ileitis I do not see how we can prove that she did not have regional ileitis at that time There are cases that have spontaneously subsided The fistula in ano and the fissure have no significance to me in the way of helping to explain this picture, or the picture which she had nineteen years after onset The fistulas of regional ileitis are perhaps suggested but not strongly enough to help Twenty-five years after onset she was operated on again and endometriosis was found, plus changes in the intestines which could not be caused by endometriosis Endometriosis can involve certain parts of the intestine, chiefly the small intestine, but not the whole colon The statement is made that the whole colon was abnormal Thirty-two years after onset she had a tumor and we are not told what brought her to the hospital, presumably an exacerbation of the same symptoms that she had been having On admission she had a stricture of the rectum, a gross deformity of the entire colon and an abdominal mass, presumably of the hepatic flexure or near it She was well developed and nourished, which is a little surprising in view of the long story of diarrhea and bleeding Her red count was over 5,000,000 which is not so surprising when we take into account the other evidences of dehydration, the dry brittle nails, parched skin, and so forth, as described

The extent of the x-ray changes in the colon rule out many of the causes of prolonged diarrhea, such as hyperthyroidism, allergy, emotional instability, achylia gastrica and the chronic bacillary dysenteries The whole colon is abnormal by x-ray There is a normal x-ray picture of the small intestine and of the stomach and duodenum, a finding which to me completely rules out regional ileitis Regional ileitis usually starts at the ileocecal valve, and always involves the small bowel, it occasionally affects the cecum and rarely patchy por-

tions of the colon, but never the entire colon with out any involvement of the small intestine This leaves four conditions to be considered Lympho granuloma inguinale can be mentioned only to be dismissed It is a common cause of rectal stricture but does not invade the whole colon Tuberculous colitis is usually a terminal complication of advanced pulmonary tuberculosis It seems conceivable that it would have caused such extensive damage in the colon in a patient with a normal chest plate Amebic dysentery may be very difficult to rule out It could be as chronic as this The failure to find amebae in the stools means but little The rectal mucosa should have shown certain characteristics, for example multiple ulcerations, with no gross deformity such as this one had She might have had more of an eosinophilia, she had 3 per cent but that is not conclusive If this diagnosis had been suspected it is probable that a course of emetine would have been tried Nothing is said about it That does not rule it out, however

I finally came to chronic idiopathic ulcerative colitis in its milder form It may be as chronic as this It is characterized by exacerbations and remissions Its greatest incidence is in young people It involves the whole colon in 93 per cent of cases, according to Rankin The rectum is almost always involved It could explain this case except for the mass in the upper abdomen Is that mass inflammatory, obstructive or neoplastic? I have tried to make Dr Holmes commit himself a little on that point, but he would not A point against neoplasm is that the second film, taken six weeks after this one in which a mass in the bowel wall is suggested, shows no evidence of tumor However, 3 per cent of patients with ulcerative colitis develop superimposed cancer, according to Bergen If it is not neoplastic it must be either inflammatory or obstructive The whole mass may have been simple distention of the bowel behind partial obstruction, which later became complete through progressive scarring, or there may have been active inflammation in the wall of the bowel at that point I cannot tell The tenderness over it is perhaps a little more suggestive of inflammatory swelling of the colon at that point My diagnosis is chronic idiopathic ulcerative colitis with possibly superimposed carcinoma at the hepatic flexure

DR. TRACY B MALLORY Are there any suggestions?

DR AUGUSTUS S ROSE I should like to ask Dr Jones or Dr McKittrick how often ulcerative colitis begins at the age of six?

DR CHESTER M JONES It is not uncommon to have it begin in children I am sure we have

seen them as young as five years of age at this hospital, and they have reported a much younger group from the Children's Hospital, Dr Urmv tells me that the disease has been described in children as young as six months. Certainly it has been reported in early childhood, if not infancy.

DR. LELAND S. MCKITTRICK: This woman represents the longest standing condition of this type that I have ever happened to see. I saw her first when she was a patient of Dr. Daniel F. Jones years ago. I saw her in that acute episode and helped him take out her appendix. The description, given here, very accurately fits the condition at that time. She later developed stricture of the rectum, which Dr. Jones used to dilate gently. Following Dr. Jones's death she came to me and later this mass in her upper abdomen was found. She was sent into the hospital for more careful investigation. Dr. Chester Jones saw her at that time. The thing which disturbed us was the fact that following the ileostomy this mass in the upper abdomen did not get smaller. It seemed to us fair to expect that, if the lesion was wholly inflammatory, draining the bowel completely through an ileostomy ought to have had a beneficial effect on the mass. A subtotal colectomy was then done. There was a large mass in relation to the first portion of the transverse colon. I could not tell whether this mass represented malignant disease. There was a small abscess in the mesentery of the bowel in that region, from which *Bacillus coli* was grown.

DR. CHESTER M. JONES: Other points might be added in view of what Dr. Rogers said. It is probably fair to state that the mass was there all the time. I agree with Dr. McKittrick that this case is unusual in that this patient had had diarrhea since the age of six but nevertheless carried out a perfectly normal life in surprising fashion. While she was described as well developed and nourished I think that is not quite right because she did have, as Dr. Rogers pointed out, very marked evidence of dehydration. It was more than dehydration; it was malnutrition. If I remember correctly she had tongue changes, evidently a certain degree of deficiency disease existed as the result of many years of malnutrition.

DR. JOHN D. STEWART: How often in a case of ulcerative colitis for twenty-five years would it be possible to dilate the sigmoid to the degree we see in the films?

DR. JONES: Ordinarily it would be a rubber-hose type and of smaller caliber than normal.

A PHYSICIAN: How is she now?

DR. MCKITTRICK: She has not been a joy in every sense of the word. I think she is going to

leave the hospital tomorrow, after a very prolonged stay.

#### CLINICAL DIAGNOSES

Chronic ulcerative colitis  
Carcinoma of the transverse colon?

#### DR. ROGERS'S DIAGNOSIS

Chronic ulcerative colitis, possibly with superimposed cancer of transverse colon

#### ANATOMICAL DIAGNOSES

Chronic ulcerative colitis  
Polyposis coli  
Adenocarcinoma, Grade II, with metastasis to regional node

#### PATHOLOGICAL DISCUSSION

DR. MALLORY: The specimen which was removed showed a typical extensive ulcerative colitis with many narrow linear ulcerations. A dozen soft polyps were scattered at irregular intervals. In the transverse colon was a frank ulcerative carcinoma, 6 cm. in length, that had extended through all layers of the bowel wall. There was a metastasis to one of the regional nodes. It was, however, a very exceptionally well-differentiated adenocarcinoma of a low grade of malignancy, therefore I think the outlook is not too hopeless.

DR. MCKITTRICK: She represents the second case, so far as I know, that we have had in the group here of carcinoma which would seem clearly to be associated with long-standing ulcerative colitis. There was a girl of twenty-two who had had an ileostomy at approximately the age of ten. She subsequently developed a massive carcinoma of the colon.

DR. MALLORY: Perhaps it is only a question of time before carcinoma develops in such a case. We do not see many cases that extend over thirty years.

DR. JONES: I should like to bring up one other point about the typical operative finding in terminal ileitis. I think there are probably more cases with involvement of the ileum than we recognize. This curious condition we call ileitis does not always warrant surgery. In many instances conservative medical treatment is definitely indicated.

DR. MALLORY: It is naturally very difficult or impossible to distinguish at some stages between ulcerative colitis and regional ileitis because it is perfectly possible, especially in children, for ulcerative colitis to pass the ileocecal valve and extend up the ileum, and also for regional ileitis to involve at least a portion of the colon.

## HARVEY CUSHING AT SEVENTY

ON April 8, 1939, Harvey Cushing will be seventy years of age. His friends from America and from distant lands will meet in New Haven, under the auspices of a group of neurologists and neurosurgeons, many of them pupils of his, the Harvey Cushing Society. To them and other guests will fall the honor of personal greetings. But the world at large will also be thinking of this great figure in American medicine, perhaps the foremost physician produced by the United States. Without being unmindful of the preceding figures in American medical history, may we not, on this occasion, honor the acknowledged leader of modern medicine? What manner of man, however, do we congratulate on his threescore years and ten?

The writings proclaim the man! His scientific contributions run from the report of his first researches (1900-1901) in the Inselspital and Hal-

lerianum at Berne under the guidance of Kocher, a physician for whom he always had the greatest admiration, to his latest and perhaps greatest work, the monograph, with Dr. Louise Eisenhardt, entitled *Meningiomas* (1938). The paper inspired by Kocher was on the subject of intracranial pressure, and the young physician, taking Kocher's advice "to see all round his subject," made a thorough investigation. A spark of interest in intracranial surgery was touched off, to grow and shine with such brilliancy for thirty-eight years that one may well say a new field of surgical treatment was disclosed and thoroughly explored by Harvey Cushing.

The first monographic report, the result of researches at the Johns Hopkins Hospital and the Hunterian Laboratory, was *The Pituitary Body and its Disorders* (1912), now a classic in medicine and a rare bibliophilic item. At the Peter Bent Brigham Hospital in Boston, monographs followed in an astoundingly regular order: *Tumors of the Nervus Acusticus and the Syndrome of the Cerebellopontile Angle* (1917), with an edition in French, published in 1924; *A Classification of the Tumors of the Glioma Group on a Histogenetic Basis with a Correlated Study of Prognosis* (1926), written with Dr. Percival Bailey, with an edition in German, published at Jena in 1930; *Studies in Intracranial Physiology and Surgery* (1926), *Tumors Arising from the Blood-Vessels of the Brain* (1928), written with Dr. Bailey; *Papers Relating to the Pituitary Body, Hypothalamus and Parasympathetic Nervous System* (1932), *Intracranial Tumours* (1932), with an edition in German, published in 1935, and one in French, in 1937, and finally, *Meningiomas: Their classification, regional behaviour, life history and surgical end results* (1938). All these works represent correlated and integrated studies, for the last volume reports cases going back to the Johns Hopkins period, and each patient is followed to date or to the termination of the individual's life. There is a distinctive style in all these books: a broad approach, documented and illustrated case histories, special and general conclusions. Although each may be used separately, together they form a picture of neuro-

surgical practice as carried on in the leading clinic of its kind in the world Truly Harvey Cushing, as only a few men have ever done, has looked "all round his subject," has profited by his mistakes of previous years and has kept the spirit of the studious investigator throughout his life

One must not, however, base judgment on a series of monographs, important as they are Innumerable scientific papers also appeared during his active life, some of the material never finding its way into the more durable monograph form An example may be given in the series of papers issued during the War, which had such a marked effect in cutting down the mortality from penetrating wounds of the brain, first in the British army and later in the American forces Under war conditions few clinical papers came fresh from the front line, "A Study of a Series of Wounds Involving the Brain and its Enveloping Structures" in the *British Journal of Surgery* (1918) was exactly that and to find a duplicate in detail illustrations and final importance would be nearly impossible Other outstanding papers were 'The Chiasmal Syndrome', papers on the posterior pituitary hormone and the parasympathetic nervous system, reports concerning trigeminal neuralgia, and, finally, his account of pituitary basophilism, now known as Cushing's syndrome The list is long, but the few noted above show the trend of the lot, each in itself of importance for an occasion and many of them permanently valuable in the history of medicine To these, moreover, should be added his contributions to the systems of surgery and medicine "Surgery of the Head" in Keen's (1908), 'Intracranial Tumors' in Osler's, 1910, revised as each edition subsequently came out Important at the time, how many general surgeons and practitioners may have been helped by the solid, sane advice therein!

On the literary side, books and papers are also abundant One easily recalls the charming prefatory note to the *Dedication Exercises of the Oscar C Tugo Circle* (1921), *The Life of Sir William Osler* (1925), *An Account of the Dedictory Ceremonies in Connection with the Base Hospital No 5 Memorial* (1928), the collected essays, *Consecratio*

*Medici and Other Papers* (1928), *The Medical Career The ideals, opportunities and difficulties of the medical profession* (1929), *The Personality of a Hospital* (1921), and the stirring *From a Surgeon's Journal* (1936) Among the papers, one re-reads most often "Realignments in Greater Medicine Their effect upon surgery and the influence of surgery upon them" (1913), "The Physician and the Surgeon" (1922), "Neurological Surgeons With the report of one case" (1923), "The Western Reserve and its Medical Traditions" (1924), 'The Doctor and His Books' (1927), "The Binding Influence of a Library on a Subdividing Profession" (1930), "Medicine at the Cross-Roads" (1933), and "The Pioneer Medical Schools of Central New York" (1934) No one should overlook, however, the scholarly and provocative "Report of the Surgeon-in-Chief," published in the annual reports of the Peter Bent Brigham Hospital from 1913 to 1931—those for 1916, 1917 and 1918 are by other hands Here he "let go" in a manner not possible under other circumstances, and one reads his inner thoughts on medical education, full-time professors, hospital management and similar topics Along formal lines these are perhaps his most important educational contributions to posterity At least, if you wish to know the man, they must be read and slowly digested, as a picture of "our time" in medicine they are invaluable

When we look at all these works, what manner of man do we see? Harvey Cushing has flown higher and sustained his flight more consistently than any of his medical contemporaries One never thinks of him as "grounded" That steady pull throughout the years in the clinic, here or abroad, is always evident, perhaps gracefully somewhat relaxed since his retirement from active neurosurgery a few years ago And yet, books, both scientific and literary, pour forth even now, for "relaxation" does not mean quite the same to this man of genius as it does to the Saturday afternoon golfer or the evening bridge player Like the Russian whose watch stopped in 1917 and to whom "all time is now tea time," to Cushing all time is work time, and because this is so today and has been

so for the last four decades, the world is richer and medicine has made a major advance

Hardly a day but that reverberations  
Of your name will ring out like a clear bell  
In times and lands now unpredictable  
Here and over unborn foreign nations,

Speaking of the brain and of its surgery,  
Workers will say 'Cushing said and Cushing did —  
Thus and so when all this was more hid  
Than now, our present, his futurity —'

Courage and genius, energy and will,  
These were little enough for you to spill  
Into the vortex that the chaos was,

Attacking the nervous system and its laws  
Unknown to many till you made them known  
Past barriers of muscle, meninx, bone!\*

#### POSTPARTUM HEMORRHAGE LACERATION OF THE CERVIX

Mrs. E. C., a thirty-five-year-old gravida V, was admitted to the hospital on November 29, 1915, at term in mild labor and with some vaginal hemorrhage.

The family history was negative, as was the patient's past history. She had never had any serious illness or operation. Catamenia began at fourteen, were regular with a twenty-eight-day cycle, and lasted four days without pain. Her last menstrual period was February 21, 1915, making the expected date of confinement November 29. Three of her previous pregnancies had resulted in normal, full-term deliveries, and the fourth had terminated with a miscarriage at the third month. Her present pregnancy had been normal until labor started, following which she had noticed persistent, profuse bloody show.

Physical examination disclosed a healthy appearing patient in mild labor. The heart was not enlarged, and the sounds were regular and of good quality, there were no murmurs. The blood pressure was 124 systolic, 76 diastolic. The lungs were

resonant, and there were no rales. Uterine contractions were coming at ten-minute intervals and lasted thirty seconds. The baby presented by the vertex in an OLA position. Rectal examination revealed the cervix to be dilated to admit one finger. There was some dark blood oozing from the vagina. The fetal heart rate was 156 and was best heard in the left lower-abdominal quadrant.

In view of the persistent hemorrhage, preparations were made for a vaginal examination. Under ether anesthesia the patient was found to have a soft cervix, which was partly taken up and dilated to two fingerbreadths. No placental tissue was felt in the lower uterine segment. A diagnosis of premature separation of a normally implanted placenta was made, and immediate delivery was considered advisable. Accordingly, the cervix was manually dilated. A forceps was then applied to the baby's head, which was found to be above the pelvic brim. The head was delivered by intermittent downward traction. The baby was in good condition.

Following the delivery of the baby there was a brisk hemorrhage. The placenta was therefore manually extracted. The hemorrhage continued, although the placenta and membranes seemed to be intact. The uterine cavity was then tightly packed with gauze. Examination of the cervix revealed a bilateral laceration, which extended out into the vault on the right side but apparently did not involve the broad ligament. Several chromic catgut sutures were inserted, and the hemorrhage subsided. The vagina was then packed tightly with gauze and treatment was immediately instituted to combat shock. The patient's pulse was 140, weak and irregular. Ergot, posterior pituitary extract, morphine and strychnine were administered. The pulse rate rapidly dropped to 112.

Twelve hours after delivery the gauze packs were removed from the vagina and uterus. There was no recurrence of hemorrhage. An intrauterine douche was then given. The patient had a temperature which ranged up to 101°F for six days but otherwise had an uneventful convalescence. She was discharged on the thirteenth postpartum day with the lacerations well healed, the uterus fairly well involuted, and the vaults free.

*Comment* This case is one more example of what not to do, and although the outcome was not so tragic as it might well have been, it is the picture that so often followed manual dilatation of the cervix. There is no mention in the history of the pulse rate before delivery. The blood pressure of 124 systolic, 76 diastolic, leads one to infer that the amount of blood lost had been quite im-

\*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

material The presence of the fetal heart beat and the normal feel of the uterus showed that if any separation of the placenta existed it was only partial In 1915 the great majority of cases that bled at the beginning of or before labor were inferred to be placenta previas, now we know that in comparison to separations of the placenta, previas are very rare The softness of this uterus and the presence of the fetal heart beat probably led the attendant to believe that a previa of some type was the cause of the bleeding

Before such a case is examined, the patient should be matched for possible transfusion, and the operating room prepared to meet that which the examination reveals If examinations of cases with placenta previa are bungled and a bagging kit and a cesarean outfit are not in readiness, too much bleeding may result before proper operation can be undertaken This column has so frequently condemned the complete manual dilatation of the undilated cervix that it is hardly necessary to state again that the operation has no place in obstetrics Of course, this case should have been either left alone, bagged or treated by artificial rupture of the membranes The brisk hemorrhage which immediately followed the birth of the baby, before placental separation, should have led to the diagnosis of a lacerated cervix The placenta should not have been immediately extracted This in itself is a serious obstetric performance Examination of the cervix would have revealed the laceration extending into the vault on the right This could have been properly sutured, and the placenta left until it had normally separated In this way the uterus would not have been invaded by the hand, it would not have been packed, and the subsequent infection would probably never have occurred

In 1915, intrauterine douches after the removal of an intrauterine pack were still commonly used Today such douches are almost never employed One has but to review the era of accouchement force and contrast it with modern-day conservatism to appreciate that operative obstetrics has not only not stood still but has made marked improvement

#### MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning April 10

##### BARNSTABLE

Sunday April 16, at 4 00 p m., at the Cape Cod Hospital, Hyannis Subject—Anemia Modern methods in diagnosis and treatment of blood

dyscrasias Instructor William P Murphy Donald E Higgins, *Chairman*

##### BERKSHIRE

Thursday, April 13, at 4 30 p m., at the House of Mercy Hospital, Pittsfield. Subject—Heart Disease The treatment of heart attacks or cardiovascular emergencies Instructor R. Earle Glendy Melvin H. Walker, Jr., *Chairman*

##### FRANKLIN

Wednesday, April 12, at 8 00 p m., at the Franklin County Public Hospital, Greenfield. Subject—Syphilis Latent syphilis—diagnosis and treatment. Instructor Francis M Thurmon Halbert G Stetson, *Chairman*

##### HAMPDEN

Thursday, April 13, at 4 00 p m., at the Academy of Medicine, Professional Building, 20 Maple Street, Springfield, and at 8 00 p m., in the Outpatient Department of the Skinner Clinic, Holyoke Hospital, Holyoke. Subject—Bleeding in the Third Trimester of Pregnancy Instructor Robert L. DeNormandie George L. Schadt, *Chairman*

##### MIDDLESEX SOUTH

Tuesday, April 11, at 4 30 p m., at the Cambridge Hospital, 330 Mt. Auburn Street, Cambridge. Subject—Operative Obstetrics Instructor Judson A Smith Alexander A. Levi, *Chairman*

##### SUFFOLK

Thursday, April 13, at 4 30 p m., in John Ware Hall, Boston Medical Library, 8 Fenway, Boston. Subject—Control and Treatment of Respiratory Infections Instructor Charles F McKhann Reginald Fitz, *Chairman*

#### LEGISLATIVE NOTES

##### PROPOSED REVISION OF HOUSE BILL 1407

##### AN ACT TO PREVENT ALIENS FROM PRACTICING MEDICINE

*Section 1* The Board of Registration in Medicine shall not examine any candidate who is an alien unless he presents to them a certificate of the Naturalization Bureau of the United States that he has declared his intention of becoming a citizen of the United States Any alien physician already registered must, within one year, present to the Board a similar certificate The Board must suspend the registration of any physician who fails to comply with this provision, the suspension to remain until the requirement is fulfilled Five years following the registration of those registered after the presentation of their certificates and five years following the presentation of the certificate of those registered previously the physician must present to the Board his completed naturalization papers The license of any physician who fails to comply with this provision must be revoked by the Board.

*Section 2* The provisions of this act shall not apply to licenses of medical students as student assistants or in terns or to the limited license of interns to practice within a hospital

CHARLES C LUND, *Chairman*

#### DEATH

DANE—JOHN DANE, M.D., of 33 Woodland Road, Jamaica Plain, died March 27 He was in his seventy fourth year

Born in Brookline, he prepared for college at Noble's School. He graduated from Harvard University and received his degree from Harvard Medical School in 1892. After serving his internship at the Massachusetts General Hospital, he became connected with the Marcella Street Home, the Boston Infants Hospital and the Boston Children's Hospital and was an assistant to the late Dr. Robert W. Lovett. He made numerous trips abroad, visiting nearly all the hospitals in England, France, Germany and Italy where orthopedic surgery was a specialty. For several years he was an instructor in orthopedics at the Harvard Medical School.

Dr. Dane was a member of the Massachusetts Medical Society and the American Medical Association.

His widow and a son survive him.

## MISCELLANY

### A RESOLUTION

The following resolution was adopted by the Massachusetts Public Health Association on January 26

WHEREAS, it has been unequivocally established that milk properly pasteurized is freed from the living bacteria responsible for tuberculosis, typhoid fever, diphtheria, scarlet fever, septic sore throat, undulant fever and other microbial diseases that may be transmitted through milk, and that the public health is more effectively safeguarded by the adoption of pasteurization for community milk supplies, and

WHEREAS, many communities in Massachusetts as well as in other states have adopted local ordinances requiring that all milk other than certified milk sold within their legal areas be pasteurized prior to being offered for sale, and

WHEREAS, Dr. Willys M. Monroe, health officer of Pittsfield, Massachusetts, in his desire to provide justifiable public-health protection to the people of that city caused an ordinance to be adopted requiring that all milk other than certified milk be properly pasteurized before being offered for sale within the city limits, and

WHEREAS, this effort to achieve recognized public health protection met with strong opposition in the city, thus necessitating carrying the case to the Supreme Judicial Court of Massachusetts, which court upheld the proposed ordinance as a reasonable requirement today for adequate public-health protection, therefore, be it

RESOLVED, that the Massachusetts Public Health Association recognizes this latest professional achievement of Dr. Monroe and commends him for his courageous and valiant effort on behalf of the public health of Pittsfield and the Commonwealth of Massachusetts and be it further

RESOLVED, that the Massachusetts Public Health Association recognizes that Dr. Monroe's efforts in this regard meet with the accepted professional requirements for adequate public health protection today, and be it further

RESOLVED, that a copy of this resolution be sent to Dr. Monroe, the Mayor of Pittsfield, Massachusetts, the *New England Journal of Medicine* and the daily press

## CORRESPONDENCE

### HISTORY OF THE IRON LUNG AND OTHER FACTS

To the Editor: The original iron lung, or the "spiropore," was first produced in 1876 by Woillez and described by him at a meeting of the Académie de Médecine (Paris) on June 20, 1876. He reported four experiences in a paper entitled, *Du spiropore, appareil de sauvetage pour le traitement de l'asphyxie, et principalement de l'asphyxie des noyés et des nouveau-nés* (*Bull Acad de med Paris* 41 611-625, 1876). He had made reference to such treatment of asphyxia in an earlier report (*Bull Acad de med Paris* 40 441-455, 1875). This iron lung was strikingly similar in appearance and identical in principle with Drinkers or Emerson's "iron lung." It consisted essentially of a steel cylinder enclosing the body of the patient, a rubber collar around the neck providing an airtight seal. Photographs of this original "iron lung," or spiropore, showing the instrument opened and closed with a patient in it, appear in the *Bulletin de l'Académie de médecine Paris* (119 82-85, 1938) and in the *Lancet* (1 237, 1939), the latter being contained in a letter by Dr. C. L. G. Pratt.

It is interesting to note that Lord Nuffield, of England, has offered to donate 500 iron lungs—one to each of the large hospitals in the British Isles, where there will be properly qualified and trained persons to supervise the use of these special machines. They will cost only about 25 or 30 pounds (less than \$150) each!

The original iron lung idea belongs to Woillez, and credit for the invention should rightfully go to him!

The Bragg-Paul Pulsator is a pneumatic jacket for applying rhythmic positive pressure, and is a very convenient and effective apparatus. The Drinker and Both machines and the Emerson modification are total enclosure instruments, the entire body, with the exception of the head, being enclosed in the apparatus. The Bragg-Paul apparatus is much preferred by some English experts to the Drinker-Emerson type. The Burstall apparatus applies negative pressure and resembles a cuirass. The Biomotor is a German apparatus. There is also an apparatus recently introduced in Sweden.

It is highly essential that, regardless of type of respirator used, especially trained persons must supervise its use. If a respirator is handled unskillfully, the patient may die! Careful teamwork is at all times necessary in these emergency cases where respirators are used.

HYMAN I. GOLDSTEIN, M.D.

1425 Broadway,  
Camden, New Jersey

### CASE 25801 AN ADDENDUM

Some of the obscurity in this interesting 'Case Record' (*New Eng J Med* 220 347-351, 1939) can be cleared up by the insertion of an additional diagnosis made when I first saw this patient December 17, 1938, the day after his admission to the hospital, but unfortunately omitted from the record as presented at the clinicopathological conference. His chief complaints on admission were vomiting, weakness and dehydration. He gave in addition, of course, the old story of heart disease, and undoubtedly there was some heart failure involved.

The chief cause of his acute illness on admission to the hospital I believed to be a toxic effect of digitalis. We estimated that he had had 89 cat units of the drug in fifty-three days. This amount was later corrected (overcor-

rected, I believe) by his physician to a somewhat lower figure, but was probably not very far from the actual dose given. Even the lower figure was above the saturation point. Thus, there was a considerable excess of digitalis, and since he was an elderly man, this effect would be more pronounced than in a younger person. There was also further evidence of the toxic effect of the digitalis in the form of marked tachycardia prior to admission, which required quinidine for control.

This important point about digitalis intoxication was not brought out in the printed record and could not of course be shown at autopsy, yet it was undoubtedly a very significant factor in the case. The toxic effect was further borne out by his improvement in the hospital after stopping the drug and following the introduction of fluids to combat the dehydration, in the absence of much evidence of congestive heart failure. Also very important as evidence was the partial heart block (P-R interval of 0.25 second) at entrance which subsided after five days (0.18-0.20 second), when he felt much better.

PAUL D WHITE M.D

Massachusetts General Hospital,  
Boston

## PNEUMONIA AND THE HEALTH OF THE NATION

*To the Editor* Your effective editorial 'Pneumonia and the Health of the Nation, March 2, 1939, calls attention to the fact that There was an excess in the [incidence] rates among families who were not on relief but whose incomes were less than \$125 per month.

The significance of this fact is well demonstrated, I believe, in a recent study of mine (A Study of the Economics of Pneumonia *United States Public Health Reports* 53 2153-2168, 1938), where the average cost of pneumonia, \$167, found in a sample of cases in New York City was contrasted with the monthly income of \$125 of half of the families in New York City. To quote from the study: It is obvious that a disease, the average cost of which when hospitalized is more than a family's monthly income, can rarely be paid for out of current family earnings.

Even when there is home instead of hospital treatment, the loss of income, if a wage-earner is affected, may put the total burden on the family up to a point which approaches the cost of a hospitalized case.

In addition to the conclusions drawn in the editorial, it becomes apparent that increased subsidization and further extension of pneumonia-control programs, based upon sound medical principles, are needed. This will remain substantially true, despite the fact that the economics of control programs may change radically with the increased use of sulfanilamide and its derivatives.

JOSEPH HIRSH, *Research Associate*

Committee on Research in Medical Economics  
9 Rockefeller Plaza,  
New York City

## REPORT OF MEETING

### TUFTS MEDICAL ALUMNI MEETING

Nearly three hundred alumni attended the annual alumni dinner of the Tufts College Medical School Association at the Hotel Somerset, Wednesday evening March 29. Speakers were Dr Alonzo K. Paine, president of the association; Mr Harold E. Sweet, president of the Trustees of Tufts College; Dean A. Warren Stearns of

the medical school; Dr Samuel H. Proger, medical director of the Joseph H. Pratt Diagnostic Hospital; and President Leonard Carmichael, of Tufts College, who delivered the main address of the evening. Dr Frederick W. O'Brien, professor of radiology, presided.

## NOTICES

### REMOVALS

JOSEPH TARTAKOFF, M.D., announces the removal of his office from 371 to 370 Commonwealth Avenue, Boston. Telephone KENmore 5480.

BENJAMIN RISEMAN, M.D., announces the removal of his office from 371 to 370 Commonwealth Avenue, Boston. Telephone KENmore 5480.

MAURICE S. SEGAL, M.D., announces the removal of his office from 371 to 370 Commonwealth Avenue, Boston. Telephone KENmore 5480.

### BOSTON CITY HOSPITAL

The monthly clinicopathological conference will be held at the Boston City Hospital on Wednesday, April 12, at 12 o'clock noon, in the Pathological Amphitheater.

JOSEPH E. HALLISEY, M.D., *Secretary*  
Medical Staff

### SOUTH END MEDICAL CLUB

The next meeting of the South End Medical Club will be held at the headquarters of the Boston Tuberculosis Association, 554 Columbus Avenue, Boston, on Tuesday, April 18, at 12 o'clock noon. Dr Joseph C. Aub will speak on Recent Advances in the Study of Internal Secretions.

Physicians are cordially invited to attend.

JOHN B. HALL, M.D., *Secretary*

### CUTTER LECTURE

Dr Frederick F. Russell, professor of preventive medicine and epidemiology emeritus of Harvard University, will give the annual Cutter Lecture in Preventive Medicine at the Harvard Medical School on Monday, April 17, at 5:00 p.m. Dr Russell's subject is 'The History of Yellow Fever as an Illustration of Methods of Study and Control of Virus Diseases.' The Cutter Lectures have been given each year since 1912. The medical profession, medical and public health students and others interested are invited to attend.

### HARVARD MEDICAL SOCIETY

The next meeting of the Harvard Medical Society will be held on Tuesday, April 11, in the amphitheater of the Peter Bent Brigham Hospital (Shattuck Street entrance), at 8:15 p.m.

#### PROGRAM

Presentation of cases

Etiology and Pathogenesis of Thyrotoxicosis. With special reference to its pituitary origin. Dr A. W. Elmer, of Lvov, Poland.

Medical students and physicians are cordially invited to attend.

ROBERT M. ZOLLINGER, M.D., *Secretary*

## NEW ENGLAND HEALTH EDUCATION INSTITUTE

The New England Health Education Institute, sponsored by the New England Health Education Association and the state departments of health and of education and the state tuberculosis associations of New England, will be held April 21 and 22 at the William Rogers Barton Building, Massachusetts Institute of Technology, 77 Massachusetts Avenue, Cambridge.

The morning session on the first day will be devoted to a general discussion of "Underlying Psychology for Motivating Health Behavior" and its application to elementary schools, secondary schools, colleges and adults. And in the afternoon various health-education problems in relation to these four groups will be considered, with a final summarization the latter part of the afternoon. Papers of general interest by Dr. Henry D. Vaughn, of Detroit, Dr. Harold D. Chope, of Newton, and Dr. Dorothy Nyswander, of New York City, will be read at the evening meeting.

The second day will consist of morning and afternoon discussions in seven sections as follows: Educational Aspects of Medical, Dental and Nursing Services in Schools, 'Evaluation of Programs, "Types of Measurement in Physical Education Programs," Problems in Health Service and Health Curriculum in Colleges," 'Publicity Methods in Public Health Education, 'Health Education in Maternal and Child Welfare, and Rural Health Education," with a summarization of the section discussions the latter part of the afternoon.

Dr. Channing Frothingham, of Boston, will be the luncheon speaker on the first day, and Dr. Howard W. Haggard, of New Haven, on the second.

The program should be of interest to many physicians, particularly those interested in public health problems and members of the district public relations committees.

Reservations for attendance at sections and for lunches should be made in advance. Since accommodations are limited, reservations will be made in the order received. Applications for registration should be made to chairmen of registration in the various states as follows: Maine, Abbie M. Buck, 256 Water Street, Augusta; New Hampshire, Dr. Mary Atchison, State Board of Health, State House, Concord; Vermont, Mrs. Alice C. Aldrich, State Department of Education, Montpelier; Massachusetts, Margaret Roberts, 661 Massachusetts Avenue, Arlington; Rhode Island, Willis E. Chandler, 139 Mathewson Street, Providence; Connecticut, Dr. Charles J. Prohaska, Department of Education, State Capitol Building, Hartford. The registration fee for the institute is \$2.00.

## DEPARTMENT OF MENTAL HEALTH RESEARCH SYMPOSIUM

The Department of Mental Health will sponsor a research symposium at the Metropolitan State Hospital, Waltham, on Friday, April 14, beginning at 10 00 a. m.

### PROGRAM

- 10 00 a. m. An Attempt to Delineate by Orderly Procedure the Clinical Findings in So-Called Dementia Praecox (Schizophrenia). Dr. Benjamin Cohen and Dr. Bardwell H. Flower. Discussed by Dr. Andras Angyal.
- 10 30 a. m. Studies on the Permeability of the Blood-Spinal Fluid Barrier During and After Metrazol Convulsions. Dr. Harry H. Michelson. Discussed by Dr. David Rothschild.

- 11 00 a. m. Observations on the Effect of Insulin-Shock Therapy on the Heart and Blood Pressure in Schizophrenia. Dr. Malcolm J. Farrell and Dr. Eteum Vassaf. Discussed by Dr. Purcell Schube.
- 11 30 a. m. Preliminary Report on the Comparative Effects of Phenobarbital and Dilantin in the Treatment of Epilepsy. Dr. Leon J. Robinson and Dr. Rudolf Osgood. Discussed by Dr. Nathaniel Showstack.
- 2 00 p. m. Is Reading Therapy? Dr. Salomon Gagnon. Discussed by Dr. Walter E. Barton.
- 2 30 p. m. Behavior Ratings for Psychiatric Patients. Dr. Paul A. Wilcox. Discussed by Dr. Henry A. Taggell.
- 3 00 p. m. The Place of the Mental Hygiene Clinic in the Community. Dr. Leo Maletz. Discussed by Dr. Grace Cragg.
- 3 30 p. m. The Use of Typhoid Antigen H as a Form of Fever Therapy in the Treatment of Cerebrospinal Syphilis. Dr. Howard T. Fiedler and Dr. Rollin V. Hadley. Discussed by Dr. Samuel H. Epstein.

## TUMOR CLINIC, BOSTON DISPENSARY

Each Tuesday and Friday morning, 10 00 to 12 30, there is a meeting of the Tumor Clinic of the Boston Dispensary, a unit of the New England Medical Center. Neoplasms of various sorts are seen and discussed, and when there is an indication, are treated with radium or high-voltage x-ray. Physicians are invited to visit this clinic. They may bring patients for aid in diagnosis or may refer patients to the clinic following which a report will be returned to the referring physician. A limited number of beds are available for diagnostic study and for treatment.

## AMERICAN ASSOCIATION OF MENTAL DEFECT

The sixty third annual convention of the American Association of Mental Defect will be held at the Palmer House in Chicago, Illinois, May 3 to May 6, inclusive.

## MEDICAL CLINIC AT THE PETER BENT BRIGHAM HOSPITAL

At 3 30 p. m. on Thursday, April 13, in the amphitheater of the Peter Bent Brigham Hospital, Dr. Joseph C. Aub will give a medical clinic. Practitioners and medical students are cordially invited to attend.

## GREATER BOSTON MEDICAL SOCIETY

A meeting of the Greater Boston Medical Society will be held in the auditorium of the Beth Israel Hospital on Wednesday, April 12, at 8 15 p. m.

Dr. Ira I. Kaplan, clinical professor of surgery, New York University Medical College and director of the Division of Cancer, New York City Department of Hospitals, will speak on "The Role of Irradiation in the Treatment of Benign and Malignant Conditions." Discussion by Drs. Harry F. Friedman, Ira F. Nathanson and Charles C. Lund will follow.

LOUIS M. FREEDMAN, M.D., *President*  
DAVID B. STEARNS, M.D., *Secretary*

## SOCIETY MEETINGS AND CONFERENCES

CALENDAR OF BOSTON DISTRICT FOR THE WEEK BEGINNING  
MONDAY, APRIL 10

## TUESDAY APRIL 11

- \*9 10 a m Joseph H Pratt Diagnostic Hospital Physical Examination of Groups Dr R. W. Buck
- \*10 a m 12 30 p m. Tumor clinic Boston Dispensary
- 12 30 p m. Hospital Council. Palmer Memorial New England Deaconess Hospital
- \*8 15 p m Harvard Medical Society Peter Bent Brigham Hospital (Shattuck Street entrance)

## WEDNESDAY APRIL 12

- \*9-10 a m Joseph H Pratt Diagnostic Hospital Hospital case presentation Dr S J Thannhauser
- 12 m Boston City Hospital Monthly clinicopathological conference Pathological amphitheater
- \*12 m Clinicopathological conference. Children's Hospital amphitheater
- 8 15 p m Greater Boston Medical Society Beth Israel Hospital auditorium.

## THURSDAY APRIL 13

- 8 30-9 30 a m Exchange visit, Surgical and Orthopedic Staffs of the Peter Bent Brigham and Children's hospitals held this week at the Children's Hospital Surgical
- \*9-10 a m Joseph H Pratt Diagnostic Hospital Metrazol Therapy in Dementia Praecox. Dr Arthur Berk.
- \*3 30 p m Medical clinic at the Peter Bent Brigham Hospital

## FRIDAY APRIL 14

- 9-10 a m Joseph H Pratt Diagnostic Hospital Here and There in Endocrinology Dr Fuller Albright
- 10 a m Department of Mental Health Research Symposium Metropolitan State Hospital Waltham
- \*10 a m 12 30 p m Tumor clinic Boston Dispensary
- 12 m Clinical meeting of the Children's Medical Service. Massachusetts General Hospital Ether Dome.

## SATURDAY APRIL 15

- \*9-10 a m Joseph H Pratt Diagnostic Hospital Hospital case presentation. Dr S J Thannhauser
- 10 a m 12 m Staff rounds of the Peter Bent Brigham Hospital Conducted by Dr Henry A. Christian

*The Newer Knowledge of Nutrition* E V McCollum, Elsa Orent Keiles and Harry G Day Fifth edition, entirely rewritten 701 pp New York The Macmillan Co, 1939 \$4.50

## BOOK REVIEWS

*Modern Surgical Technique* Max Thorek. 2045 pp Complete in 3 vol Philadelphia, London, Montreal and New York J B Lippincott Co, 1938 \$33.00

In this three volume work the author describes the technique of operations in every department of surgery, including ophthalmology. It is profusely illustrated with very good drawings, many by Shepard, and photographs which reflect the author's well-known ability in that field. Unfortunately, like many similar books, discrimination is lacking in the presentation of many operations. For example, the rarely performed Lisfranc and Syme's amputations receive as much space as the common mid thigh amputations. Also, in the section on plastic surgery, considerable attention is paid to the generally abandoned procedures of heterografting and zoografting, with direc

## NEW ENGLAND HEALTH EDUCATION INSTITUTE

The New England Health Education Institute, sponsored by the New England Health Education Association and the state departments of health and of education and the state tuberculosis associations of New England, will be held April 21 and 22 at the William Rogers Barton Building, Massachusetts Institute of Technology, 77 Massachusetts Avenue, Cambridge.

The morning session on the first day will be devoted to a general discussion of "Underlying Psychology for Motivating Health Behavior" and its application to elementary schools, secondary schools, colleges and adults. And in the afternoon various health-education problems in relation to these four groups will be considered, with a final summarization the latter part of the afternoon. Papers of general interest by Dr. Henry D. Vaughn, of Detroit, Dr. Harold D. Chope, of Newton, and Dr. Dorothy Nyswander, of New York City, will be read at the evening meeting.

The second day will consist of morning and afternoon discussions in seven sections as follows: Educational Aspects of Medical, Dental and Nursing Services in Schools, 'Evaluation of Programs,' 'Types of Measurement in Physical Education Programs,' 'Problems in Health Service and Health Curriculum in Colleges,' 'Publicity Methods in Public Health Education,' 'Health Education in Maternal and Child Welfare,' and 'Rural Health Education,' with a summarization of the section discussions the latter part of the afternoon.

Dr. Channing Frothingham, of Boston, will be the luncheon speaker on the first day, and Dr. Howard W. Haggard, of New Haven, on the second.

The program should be of interest to many physicians, particularly those interested in public health problems and members of the district public relations committees.

Reservations for attendance at sections and for luncheons should be made in advance. Since accommodations are limited, reservations will be made in the order received. Applications for registration should be made to chairmen of registration in the various states as follows: Maine, Abbie M. Buck, 256 Water Street, Augusta; New Hampshire, Dr. Mary Atchison, State Board of Health, State House, Concord; Vermont, Mrs. Alice C. Aldrich, State Department of Education, Montpelier; Massachusetts, Margaret Roberts, 661 Massachusetts Avenue, Arlington; Rhode Island, Willis E. Chandler, 139 Mathewson Street, Providence; Connecticut, Dr. Charles J. Prohaska, Department of Education, State Capitol Building, Hartford. The registration fee for the institute is \$2.00.

## DEPARTMENT OF MENTAL HEALTH RESEARCH SYMPOSIUM

The Department of Mental Health will sponsor a research symposium at the Metropolitan State Hospital, Waltham, on Friday, April 14, beginning at 10 00 a m.

## PROGRAM

- 10 00 a m An Attempt to Delineate by Orderly Procedure the Clinical Findings in So-Called Dementia Praecox (Schizophrenia) Dr. Benjamin Cohen and Dr. Bardwell H. Flower. Discussed by Dr. Andras Angyal.
- 10 30 a m Studies on the Permeability of the Blood-Spinal Fluid Barrier During and After Metrazol Convulsions Dr. Harry H. Michelson. Discussed by Dr. David Rothschild.

- 11 00 a m Observations on the Effect of Insulin-Shock Therapy on the Heart and Blood Pressure in Schizophrenia Dr. Malcolm J. Farrell and Dr. Eteum Vassaf. Discussed by Dr. Purcell Schube.
- 11 30 a m Preliminary Report on the Comparative Effects of Phenobarbital and Dilantin in the Treatment of Epilepsy Dr. Leon J. Robinson and Dr. Rudolf Osgood. Discussed by Dr. Nathaniel Showstack.
- 2 00 p m Is Reading Therapy? Dr. Salomon Gagnon. Discussed by Dr. Walter E. Barton.
- 2 30 p m Behavior Ratings for Psychiatric Patients. Dr. Paul A. Wilcox. Discussed by Dr. Henry A. Tadgell.
- 3 00 p m The Place of the Mental Hygiene Clinic in the Community Dr. Leo Maletz. Discussed by Dr. Grace Cragg.
- 3 30 p m The Use of Typhoid Antigen H as a Form of Fever Therapy in the Treatment of Cerebrospinal Syphilis Dr. Howard T. Fiedler and Dr. Rollin V. Hadley. Discussed by Dr. Samuel H. Epstein.

## TUMOR CLINIC, BOSTON DISPENSARY

Each Tuesday and Friday morning, 10 00 to 12.30, there is a meeting of the Tumor Clinic of the Boston Dispensary, a unit of the New England Medical Center. Neoplasms of various sorts are seen and discussed, and when there is an indication, are treated with radium or high-voltage x ray. Physicians are invited to visit this clinic. They may bring patients for aid in diagnosis or may refer patients to the clinic following which a report will be returned to the referring physician. A limited number of beds are available for diagnostic study and for treatment.

## AMERICAN ASSOCIATION OF MENTAL DEFECT

The sixty third annual convention of the American Association of Mental Defect will be held at the Palmer House in Chicago, Illinois, May 3 to May 6, inclusive.

## MEDICAL CLINIC AT THE PETER BENT BRIGHAM HOSPITAL

At 3 30 p m on Thursday, April 13, in the amphitheater of the Peter Bent Brigham Hospital, Dr. Joseph C. Aub will give a medical clinic. Practitioners and medical students are cordially invited to attend.

## GREATER BOSTON MEDICAL SOCIETY

A meeting of the Greater Boston Medical Society will be held in the auditorium of the Beth Israel Hospital on Wednesday, April 12, at 8 15 p m.

Dr. Ira I. Kaplan, clinical professor of surgery, New York University Medical College and director of the Division of Cancer, New York City Department of Hospitals, will speak on 'The Role of Irradiation in the Treatment of Benign and Malignant Conditions.' Discussion by Drs. Harry F. Friedman, Ira F. Nathanson and Charles C. Lund will follow.

## BRONCHOSCOPIC DILATATION OF BRONCHIAL STENOSIS FOLLOWING THORACOPLASTY FOR TUBERCULOSIS\*

EDWARD B. BENEDICT, M.D.†

BOSTON

RELATIVELY little has been written about bronchoscopy in tuberculosis, though it is generally recognized that bronchoscopy is indicated in bronchial obstruction, whether due to tuberculosis or other pathologic lesions. Jackson<sup>1</sup> mentions complete bronchial occlusion by cheesy pus and debris from a tuberculous peribronchial node that had eroded through the bronchus. Clerf<sup>2</sup> believes that bronchoscopy is indicated in tuberculosis when unexplained symptoms such as wheezing or dyspnea occur. In cases where tuberculosis was unsuspected he established a positive diagnosis of pulmonary tuberculosis by bronchoscopy. Eloesser<sup>3</sup> has found bronchial stenosis to be frequently due to various tuberculous processes, and has made many bronchoscopic examinations in tuberculosis without ill effect. Myerson<sup>4</sup> reports a series of 60 cases of pulmonary tuberculosis where bronchoscopy was performed, and says that "in not a single instance was there an exacerbation of the disease or a spread to a new area of the lung following bronchoscopy." Ballou<sup>5</sup> has performed bronchoscopy because of the development of asthmatic symptoms in known cases of pulmonary tuberculosis; improvement has resulted from dilatation of stenosis and removal of granulation tissue. Samson<sup>6</sup> in a recent discussion of tuberculous tracheobronchitis states: "Bronchoscopically four types of lesions are distinguishable, two or more of which may co-exist in the same patient." These four types are the non-ulcerative and non-stenotic, the hyperplastic, the ulcerative and the stenotic.

With regard to the pathogenesis of tuberculous stenosis of the bronchus following thoracoplasty, it seems probable that some degree of tuberculous tracheobronchitis exists before thoracoplasty is undertaken, and that the collapse of the lung, with possible kinking and compression of the bronchi, results in an approximation of the bronchial sur-

faces, local spread of the tuberculous process, ulceration and stenosis. Samson<sup>6</sup> and his co-workers believe that the ulcerative type of tracheobronchial tuberculosis is more active and virulent than the non-ulcerative, and state that "because of the obviously poor prognosis we do not now recommend any type of collapse therapy for patients with ulcerative tracheobronchial lesions unless subsequent bronchoscopic examinations demonstrate a tendency for the ulcers to heal without the formation of an important stenosis." They believe that collapse therapy is not a responsible etiologic agent. It seems to me that we must postulate a pre-existing tracheobronchial tuberculosis which may well have been activated by the collapse procedure. The importance of bronchoscopy before collapse therapy is undertaken is therefore self-evident in any case where there is a suspicion of tracheobronchial tuberculosis.

Three cases of bronchial stenosis following thoracoplasty for tuberculosis, reported below, have recently come under my care for bronchoscopic examination and treatment. Unfortunately none of the patients had had a preoperative diagnostic bronchoscopy, because the thoracoplasties were performed before the importance of this preliminary procedure had become recognized.

### CASE REPORTS

*Case 1.* E. H. (U No. 85643), a 40-year-old, married, American housewife, entered the Massachusetts General Hospital for bronchoscopy on October 22, 1936. She gave an 8-year history of pulmonary tuberculosis involving the entire right upper lobe, treated at Rutland State Sanatorium and Mattapan Sanatorium with pneumothorax. A right phrenicectomy was done in 1933. First, second and third stage thoracoplasties were done in 1934, following which the patient was discharged home on bed rest, but had intermittent episodes of fever, cough and raising of sputum. On October 4, 1935, x-ray examination of the chest with Lipiodol showed normal filling of the left bronchial tree. The right main bronchus showed a cone-shaped stenosis (Fig. 1) starting about 1 cm. beyond the bifurcation. From October, 1935, to October, 1936, the

tions for the transplantation of skin from the greyhound, chicken and frog to human beings. This section, like many others in the book, is studded with unfamiliar names, but with relatively few references to the literature for the curious student. On the other hand, no mention is made of such common and much discussed procedures as the injection treatment of hernia or the internal fixation of fractures of the neck of the femur.

Electrosurgery is vigorously championed throughout, particularly in the chapter on surgery of the liver and gall bladder where the author's operation, cholecysto-electrocoagulectomy, is well described. Certain statements are difficult to explain, for example, on page 1609 it is stated: "Exploration of the biliary passages should be omitted in the presence of jaundice."

The book should be useful for the surgeon called on to perform an operation with which he is unfamiliar, but it is not recommended for the beginner or occasional operator.

---

*The Surgical Treatment of Hypertension* George Crile.  
239 pp Philadelphia and London W B Saunders  
Co, 1938 \$4.00

In his most recent book Dr Crile carries on further with a theme which has interested him for many years. This was first presented in an Ether Day Address at the Massachusetts General Hospital in 1910 entitled "Phylogenetic Association in Relation to Certain Medical Problems." In 1934, his writings and thoughts on this general subject were gathered together in a volume *Diseases Peculiar to Civilized Man*. His latest work is a fitting sequel to this, it presents a theory concerning the etiology of essential hypertension and discusses the early results of celiac ganglionectomy.

Regarding the rationale of this procedure, his theory appears to be a colorful restatement of the neurogenic theory of the origin of essential hypertension. This has been discussed in detail by Fishberg, and is well known by those interested in this disease. Whether hypertension is actually of neurogenic origin or whether it is the result of primary changes in the peripheral vascular bed is still unknown.

The actual performance of the operation may be described as somewhat of a sleight-of-hand performance. While the technic may be feasible in Dr Crile's hands, it does not appear to be one which should be recommended to others. It would appear that adequate surgical exposure of the celiac ganglia for the purpose of their removal could be obtained in a more satisfactory manner than that used by Dr Crile.

Although the operation is different from most of those previously advocated, its object is really quite similar. All other procedures aim to denervate the splanchnic bed but in general do not necessitate removal of the celiac ganglia. Experience has shown that the best results of sympathectomy are obtained by resection of the preganglionic portion of the motor pathway, rather than by resecting the postganglionic pathway or removing the ganglia in which the synapses lie. Thus celiac ganglionectomy is a postganglionic rather than a preganglionic section. All other procedures involve a preganglionic section. Whether this will make any essential difference in the results in this disease, time alone will tell.

Turning to the actual results, we find that Dr Crile's figures are quite similar to those generally reported in any unselected group of cases. The follow-up is of very short duration—a few months in most cases, somewhat over 1 year in others. No results of as long as two years

duration are given. Most observers would hesitate to draw definite conclusions from these data.

Regarding selection of cases, Dr Crile believes that the patient as a whole must be considered. Thus, physiologic age rather than actual age, the duration of the disease, the stage of the disease, the state of the eyes, heart, and kidneys, and the response to sedation, all must be evaluated. This is in keeping with the feeling of most observers.

Dr Crile believes that after a certain stage of sclerosis has been reached, even if the cause is removed, an irreversible state persists. Even so, he finds that operation may be indicated, largely for symptomatic relief which he obtained in 87 per cent of cases. Some would agree and some would disagree with this.

Seventeen per cent of his cases had normal blood pressure one year after operation. This figure is not significant in a series of unselected patients such as his.

The reviewer believes that the value of any operation for this disease should be judged almost solely by the effect on the blood pressure level. Symptomatic relief is not sufficient justification for surgery. An attempt should be made to select cases which will respond. If further observation of good results shows them to be lasting or permanent, and not accompanied by any deleterious effects on any organs or tissues of the body, then one may fairly conclude that sympathectomy is of real value in the treatment of essential hypertension. Whether the most effective operation has as yet been devised, is still a question.

---

*The Treatment of Fractures* Charles L. Scudder Eleventh  
edition 1208 pp Philadelphia and London W B  
Saunders Co, 1938 \$12.00

Progress in fracture treatment calls for constant revision of one's ideas, and the fact that the author, who has been one of the foremost exponents of what has been best in the treatment of fractures, believed that this, his eleventh edition, was called for in order to keep the work up to the times, is conclusive proof that there must be much that is new. The chapter on the use of the fluoroscope in the reduction of fractures is a timely one for those who are not alive to the latent dangers and do not take precautions to avoid them. The various types of skeletal traction and the indications for their employment are well considered, as are the numerous devices for both ambulatory and bed treatment, by extension and counterextension.

Chapters on Birth Fractures, Epiphyseal Injuries, "Initial Care and Transportation, Plaster of Paris Splints, Ambulatory Management, 'The Healing of Fractures, 'Pathological Fractures, Open or Compound Fractures, 'Traumatic Shock, Operative Treatment, Qualifications of the Surgeon for the Operative Treatment and Anaesthesia are all of importance and receive excellent treatment by the author's collaborators.

The chapters on methods of fixation and surgical approach to the various fractured bones cover the modern methods of dealing with the different fractures, and special sections are devoted to fractures of the facial bones, head injuries, fractures and dislocations of the vertebral column, injuries to the intervertebral disks, Volkmann's contracture and medicolegal relations. The other chapters on the common fractures and their unusual and exceptional features are brought up to date. All are well illustrated and arranged in an orderly manner for easy reference. This edition maintains the high standard attained by previous editions and holds its own in a field in which there are many worthy competitors.

## BRONCHOSCOPIC DILATATION OF BRONCHIAL STENOSIS FOLLOWING THORACOPLASTY FOR TUBERCULOSIS\*

EDWARD B. BENEDICT, M.D. †

BOSTON

RELATIVELY little has been written about bronchoscopy in tuberculosis, though it is generally recognized that bronchoscopy is indicated in bronchial obstruction, whether due to tuberculosis or other pathologic lesions. Jackson<sup>1</sup> mentions complete bronchial occlusion by cheesy pus and debris from a tuberculous peribronchial node that had eroded through the bronchus. Clerf<sup>2</sup> believes that bronchoscopy is indicated in tuberculosis when unexplained symptoms such as wheezing or dyspnea occur. In cases where tuberculosis was unsuspected he established a positive diagnosis of pulmonary tuberculosis by bronchoscopy. Eloesser<sup>3</sup> has found bronchial stenosis to be frequently due to various tuberculous processes, and has made many bronchoscopic examinations in tuberculosis without ill effect. Myerson<sup>4</sup> reports a series of 60 cases of pulmonary tuberculosis where bronchoscopy was performed, and says that "in not a single instance was there an exacerbation of the disease or a spread to a new area of the lung following bronchoscopy." Ballou<sup>5</sup> has performed bronchoscopy because of the development of asthmatic symptoms in known cases of pulmonary tuberculosis, improvement has resulted from dilatation of stenosis and removal of granulation tissue. Samson<sup>6</sup> in a recent discussion of tuberculous tracheobronchitis states "Bronchoscopically four types of lesions are distinguishable, two or more of which may co-exist in the same patient." These four types are the non-ulcerative and non-stenotic, the hyperplastic, the ulcerative and the stenotic.

With regard to the pathogenesis of tuberculous stenosis of the bronchus following thoracoplasty, it seems probable that some degree of tuberculous tracheobronchitis exists before thoracoplasty is undertaken, and that the collapse of the lung, with possible kinking and compression of the bronchi, results in an approximation of the bronchial sur-

faces, local spread of the tuberculous process, ulceration and stenosis. Samson<sup>6</sup> and his co-workers believe that the ulcerative type of tracheobronchial tuberculosis is more active and virulent than the non-ulcerative, and state that "because of the obviously poor prognosis we do not now recommend any type of collapse therapy for patients with ulcerative tracheobronchial lesions unless subsequent bronchoscopic examinations demonstrate a tendency for the ulcers to heal without the formation of an important stenosis." They believe that collapse therapy is not a responsible etiologic agent. It seems to me that we must postulate a pre-existing tracheobronchial tuberculosis which may well have been activated by the collapse procedure. The importance of bronchoscopy before collapse therapy is undertaken is therefore self-evident in any case where there is a suspicion of tracheobronchial tuberculosis.

Three cases of bronchial stenosis following thoracoplasty for tuberculosis, reported below, have recently come under my care for bronchoscopic examination and treatment. Unfortunately none of the patients had had a preoperative diagnostic bronchoscopy, because the thoracoplasties were performed before the importance of this preliminary procedure had become recognized.

### CASE REPORTS

*Case 1.* E. H. (U No. 85643), a 40-year-old, married, American housewife, entered the Massachusetts General Hospital for bronchoscopy on October 22, 1936. She gave an 8-year history of pulmonary tuberculosis involving the entire right upper lobe, treated at Rutland State Sanatorium and Mattapan Sanatorium with pneumothorax. A right phrenicectomy was done in 1933. First, second and third stage thoracoplasties were done in 1934, following which the patient was discharged home on bed rest, but had intermittent episodes of fever, cough and raising of sputum. On October 4, 1935, x-ray examination of the chest with Lipiodol showed normal filling of the left bronchial tree. The right main bronchus showed a cone-shaped stenosis (Fig. 1) starting about 1 cm. beyond the bifurcation. From October, 1935, to October, 1936, the

\*From the Massachusetts General Hospital, Boston.

†Assistant in surgery, Harvard Medical School; assistant surgeon, Massachusetts General Hospital.

patient continued bed rest at home, having repeated attacks of fever, ranging up to 103°F, with severe cough and a moderate amount of sputum, which was, however, negative for tubercle bacilli.

Because of the x-ray picture of stenosis and the repeated attacks of cough and fever, bronchoscopy was advised and was performed on October 22, 1936. About 1 cm below the carina the right main bronchus was com-

tacks of fever, cough or abnormal amounts of sputum suggesting bronchial obstruction. She gained weight and strength, was up and about and felt like a different individual.

Bronchoscopy on October 14, 1937, showed the sinus to be closed again at its lower end. In view of the great clinical improvement it was assumed that the cavity had fibrosed and no attempt was made to reopen it. Six months later, however, several more attacks of bronchial obstruction occurred, necessitating bronchoscopy on September 29, 1938, at which time the stenosis was again dilated and a considerable amount of thick secretion was aspirated from the bronchus beyond the stenosis. Following this procedure the patient was greatly relieved and has had no further attacks. We believe that bronchoscopy should be repeated in this case about every 3 months in order to prevent recurrent stenosis.

**Case 2** E. J. B. (U No 9232), a 22-year-old, single woman, entered the Massachusetts General Hospital for bronchoscopy on October 22, 1936. She gave a 5-year history of pulmonary tuberculosis, with positive sputum, involving only the right apex, and treated at Rutland State Sanatorium. A right phrenectomy was done in 1932. A right upper thoracoplasty was done in 1934. Six to 8 weeks following thoracoplasty the patient developed coughing

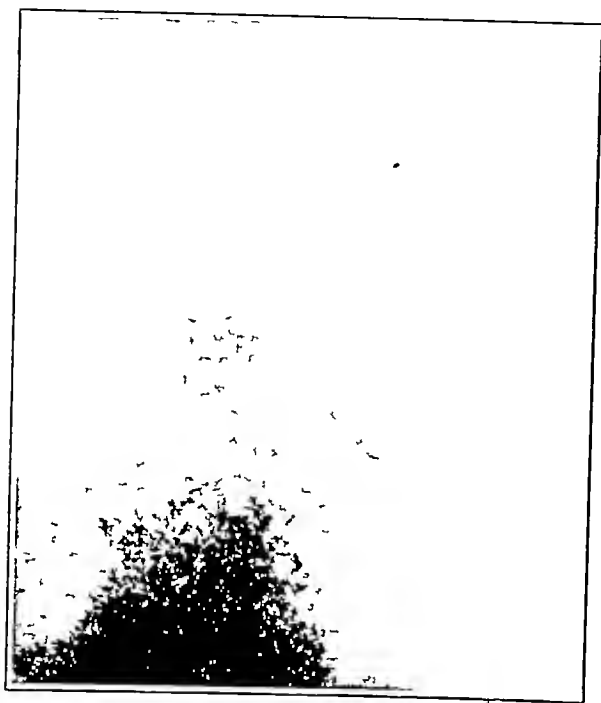

FIGURE 1 Case 1

*X-ray film after Lipiodol injection demonstrating a cone-shaped area above complete stenosis of right main bronchus*

pletely occluded except for a circular opening about 2 mm in diameter. There was no evidence of inflammation in this region and no secretion. A very small (No 8) soft rubber esophageal bougie was introduced into this opening, and seemed to meet complete obstruction when advanced about 3 cm. Larger bougies up to No 11 were introduced and the sinus tract was gently dilated. It was found that bougies could be introduced farther and farther, and finally a small one apparently went in about 6 cm to a definite cavity, from which a considerable amount of mucopurulent material was aspirated. Following bronchoscopy the patient felt much better and had much less coughing. On November 5, 1936, bronchoscopy was repeated. The sinus was found to be wider open than before, and soft bougies up to No 14 were passed through to the cavity without difficulty. Two weeks later bronchoscopic dilatation was again done and the secretion was aspirated into a collector. The stained smear was negative for tubercle bacilli. The same material was injected into a guinea pig, which was also reported negative for tuberculosis. On December 17, 1936, bronchoscopic dilatation was repeated and bougies up to No 16 passed easily through the sinus into the cavity. Smears and guinea pig injection were again negative. Following these bronchoscopic treatments x-ray examination with Lipiodol showed the fistulous tract to fill beyond the stenosis (Fig 2). For 10 months the patient had no further at-

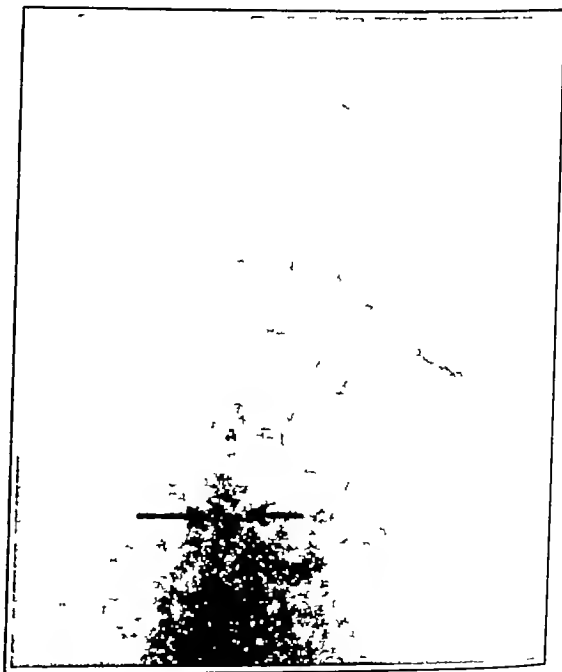

FIGURE 2 Case 1

*X-ray film after Lipiodol injection and after bronchoscopic treatment showing dilatation of sinus tract and the formation of a small cavity*

spells, raising daily about 200 cc. of rather thick, foul sputum. Similar coughing attacks occurred about every 4 months. She was obliged to restrict her activities very markedly. X-ray examination (Fig 3) on September 16, 1936, showed an area of density at the right apex consistent with collapse of the right upper lobe due to occlusion of the bronchus. Lipiodol injection (Fig 4) confirmed this, showing the right upper lobe bronchus to be completely obstructed.

Because of the coughing attacks and x-ray findings,

bronchoscopy was performed on October 22, 1936, and showed the right upper lobe orifice to be reddened and edematous. By means of the Henning esophagoscope, which permits right angle vision into an upper lobe bronchus, a stenosis of the bronchus was demonstrable. This was dilated with esophageal bougies, Nos. 11 to 18, which entered the upper lobe bronchus for about 5 cm. There was very little secretion. Bronchoscopy was repeated on November 18, 1936, and on December 10, 1936, the right upper lobe bronchus being dilated each time. Following these treatments there was less sputum than formerly and it was more easily raised. X-ray examination (Fig. 5) in March, 1937, showed much better aeration at the right apex. Sputum examination was negative for tubercle bacilli. The patient was last seen in June, 1938, a year and a half after the last bronchoscopic treatment, she was feeling very well and had had no further attacks of cough, fever or abnormal amounts of sputum. She had been attending art school for the past 9 months.

*Case 3* F. E. F. (U No. 3581), a 36-year-old single woman, entered the Massachusetts General Hospital for bronchoscopy on October 29, 1936. She gave a 14-year history of pulmonary tuberculosis, with positive sputum, involving the entire right lung, and treated at the Rutland

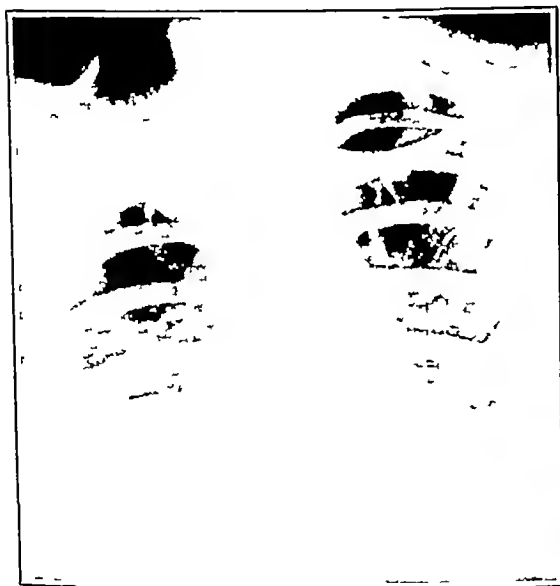

FIGURE 3 *Case 2*

*X-ray film of chest showing density of right apex due to collapse of the right upper lobe*

State Sanatorium. A right phrenicectomy was done in 1930. In 1931 a two-stage complete right thoracoplasty was done, followed 2 years later by an anterolateral thoracoplasty. Three years later (April, 1936) she began having recurrent colds with fever every 2 weeks, which completely incapacitated her for work. Because of these repeated attacks it was suspected that there was intermittent bronchial obstruction, and bronchoscopy was recommended and was performed October 29, 1936. The right upper lobe orifice was found reddened and narrowed. Soft rubber esophageal dilators were passed into the right upper lobe bronchus for about 3 cm and a small amount of thick secretion was aspirated. For 4 weeks following

bronchoscopy the patient had no signs of obstruction and no colds, and was able to raise sputum more easily. About December 1, however, she had another cold, which was less severe than formerly. Bronchoscopy was repeated on December 17, at which time there was observed a small, whitish plaque of fibrin near the right upper lobe orifice toward the anterior inferior aspect. A small amount of white secretion was collected from this region, which on smear was reported negative for tubercle bacilli. Some of this secretion was injected into a guinea pig, which was reported negative for tuberculosis. The trachea in the

FIGURE 4 *Case 2*

*X-ray film after Lipiodol injection showing complete obstruction of the right upper lobe bronchus*

region of the upper lobe orifice and above it was somewhat reddened and granular. By means of the Henning right angle vision esophagoscope, introduced through the bronchoscope, a view of the right upper lobe bronchus was obtained, which showed it to be reddened and so narrowed that its bifurcation could not be seen. Esophageal dilators Nos. 8, 10, 14 and 16, were passed into this bronchus. There was very little secretion. Bronchoscopy was repeated in May 1937. Following bronchoscopy the patient raised sputum much more easily and had only two colds over a period of 1 year. She showed marked improvement in strength and was able to return to light work. Three months later, however (September, 1938) it was necessary to repeat the bronchoscopic treatment because of pain in the right manubrial region and difficulty in raising sputum. Bronchoscopy should be repeated in this case about every 3 months.

patient continued bed rest at home, having repeated attacks of fever, ranging up to  $103^{\circ}\text{F}$ , with severe cough and a moderate amount of sputum, which was, however, negative for tubercle bacilli.

Because of the x-ray picture of stenosis and the repeated attacks of cough and fever, bronchoscopy was advised and was performed on October 22, 1936. About 1 cm below the carina the right main bronchus was com-

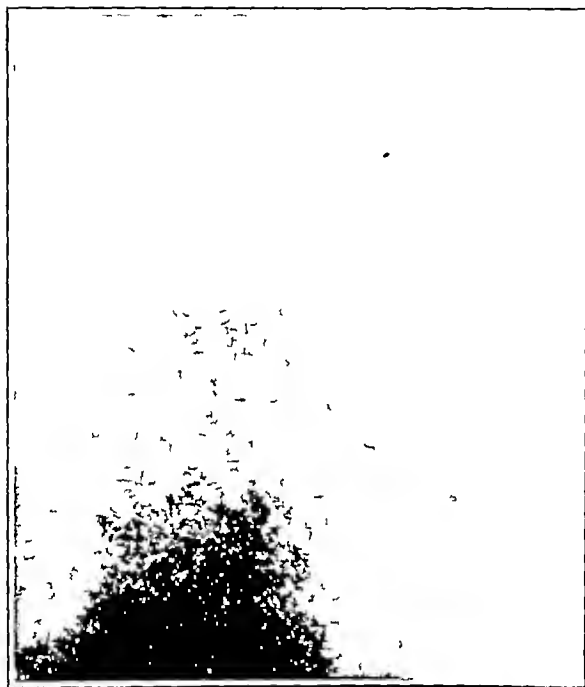

FIGURE 1 Case 1

*X-ray film after Lipiodol injection demonstrating a cone shaped area above complete stenosis of right main bronchus*

pletely occluded except for a circular opening about 2 mm. in diameter. There was no evidence of inflammation in this region and no secretion. A very small (No 8) soft-rubber esophageal bougie was introduced into this opening, and seemed to meet complete obstruction when advanced about 3 cm. Larger bougies up to No 11 were introduced and the sinus tract was gently dilated. It was found that bougies could be introduced farther and farther, and finally a small one apparently went in about 6 cm. to a definite cavity, from which a considerable amount of mucopurulent material was aspirated. Following bronchoscopy the patient felt much better and had much less coughing. On November 5, 1936, bronchoscopy was repeated. The sinus was found to be wider open than before, and soft bougies up to No 14 were passed through to the cavity without difficulty. Two weeks later bronchoscopic dilatation was again done and the secretion was aspirated into a collector. The stained smear was negative for tubercle bacilli. The same material was injected into a guinea pig, which was also reported negative for tuberculosis. On December 17, 1936, bronchoscopic dilatation was repeated and bougies up to No 16 passed easily through the sinus into the cavity. Smears and guinea pig injection were again negative. Following these bronchoscopic treatments x-ray examination with Lipiodol showed the fistulous tract to fill beyond the stenosis (Fig 2). For 10 months the patient had no further at-

tacks of fever, cough or abnormal amounts of sputum suggesting bronchial obstruction. She gained weight and strength, was up and about and felt like a different individual.

Bronchoscopy on October 14, 1937, showed the sinus to be closed again at its lower end. In view of the great clinical improvement it was assumed that the cavity had fibrosed and no attempt was made to reopen it. Six months later, however, several more attacks of bronchial obstruction occurred, necessitating bronchoscopy on September 29, 1938, at which time the stenosis was again dilated and a considerable amount of thick secretion was aspirated from the bronchus beyond the stenosis. Following this procedure the patient was greatly relieved and has had no further attacks. We believe that bronchoscopy should be repeated in this case about every 3 months in order to prevent recurrent stenosis.

**Case 2** E J B (U No 9232), a 22 year-old, single woman, entered the Massachusetts General Hospital for bronchoscopy on October 22, 1936. She gave a 5-year history of pulmonary tuberculosis, with positive sputum, involving only the right apex, and treated at Rutland State Sanatorium. A right phrenicectomy was done in 1932. A right upper thoracoplasty was done in 1934. Six to 8 weeks following thoracoplasty the patient developed coughing

FIGURE 2 Case 1

*X-ray film after Lipiodol injection and after bronchoscopic treatment showing dilatation of sinus tract and the formation of a small cavity*

spells, raising daily about 200 cc. of rather thick, foul sputum. Similar coughing attacks recurred about every 4 months. She was obliged to restrict her activities very markedly. X-ray examination (Fig 3) on September 16, 1936, showed an area of density at the right apex consistent with collapse of the right upper lobe due to occlusion of the bronchus. Lipiodol injection (Fig 4) confirmed this, showing the right upper lobe bronchus to be completely obstructed.

Because of the coughing attacks and x-ray findings,

## ARACHNODACTYLY ITS OCCURRENCE IN SEVERAL MEMBERS OF ONE FAMILY\*

JAMES HARRISON, M.D.,† AND MAX J. KLAINER, M.D.‡

BOSTON

**A**RACHNODACTYLY or Marfan's syndrome was first described by Marfan in 1896.<sup>1</sup> Since that time there have been numerous references to this disease in European literature, and over 100 cases have been described.<sup>2-7</sup> In America, however, the syndrome was first reported by Piper and Irvine-Jones in 1926,<sup>8</sup> and up to this year we have found only 8 such cases completely described in the American literature.<sup>9-11</sup> During the current year 10 additional cases have been reported.<sup>12-13</sup> We are not including in our figures the several cases reported by ophthalmologists,<sup>14-15</sup> who devote almost their entire description to the ocular abnormalities.

The syndrome embodies a group of developmental defects affecting chiefly the tissues of mesodermal origin, such as the bones, ligaments, tendons, muscles, fat and heart. The major characteristics of the disease are (1) long slender fingers and toes, with a tendency toward claw hands and feet (this first called Marfan's attention to the condition and has given rise to its generally accepted name), (2) underdevelopment of the musculature, with decrease in subcutaneous fat, relaxation of the ligaments and elongation of the tendons, (3) defects in the bony system giving rise to kyphosis, scoliosis, deformities of the sternum and asymmetry of the thorax, (4) congenital abnormalities of the heart, (5) highly arched palate with poor development of the teeth, (6) deformities of the ear lobes, and (7) ocular abnormalities, especially dislocation of the lens with a tendency toward iridodonesis and high myopia. In addition, the pupillary reflexes tend to be sluggish, the pupils react poorly to mydriatics and there is deep physiologic cupping of the disks. It is rare to find a case showing all these abnormalities, but several of them are usually present.

The etiology of the condition is unknown. Various authors<sup>4-9</sup> have mentioned endocrine disorders, mongolism, defects in the development of the neural tube, defects in the germ plasma, and so forth. The consensus is that the disease is hereditary and familial, and develops in intrauterine life. The purpose of this paper is to report a typical case of arachnodactyly showing prac-

tically all the deformities, and to mention several other members of the same family showing similar defects, thus bringing out the hereditary and familial aspects of the disease.

### CASE REPORT

A 6-year-old girl (Case 30380) was admitted to the Haynes Memorial Hospital in October, 1938, with a mild scarlet fever, from which she recovered without complications.

At birth, this patient, the last of twelve pregnancies, was a "blue baby" and markedly edematous. At the age of 1

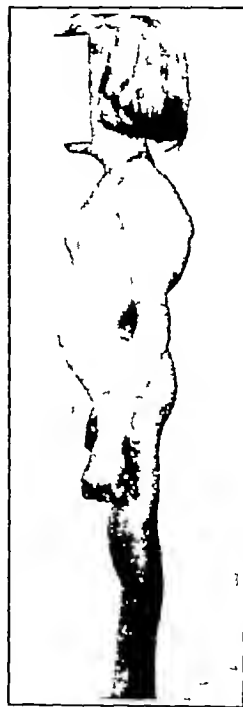

FIGURE 1 Photograph of the Patient

*This view shows the pigeon breast, the dorsal scolio-kyphosis and the long thin extremities.*

month contracture of the fingers was noted. At 6 months the presence of a heart murmur, a pigeon breast and dorsolumbar scoliosis was detected. During infancy the child had measles, German measles and whooping cough, and at the age of 4 a severe case of bronchopneumonia. She had always been underdeveloped and delicate, and because of her deformities had attended an outpatient clinic, where along with orthopedic measures she was given a high vitamin diet for rickets.

Physical examination disclosed a poorly developed and nourished child, intelligent and co-operative, with sunken eyes, marked skeletal deformities, long limbs and long, slender fingers with claw hands. She was 44½ inches tall but weighed only 33 pounds. The skull was dolicho-

## DISCUSSION

It should not be inferred from the good results obtained in these 3 patients that we believe the treatment of tracheobronchial tuberculosis to be always an easy matter. Although there will be some failures, we certainly cannot agree with Myerson<sup>8</sup> that successful dilatation of tuberculous

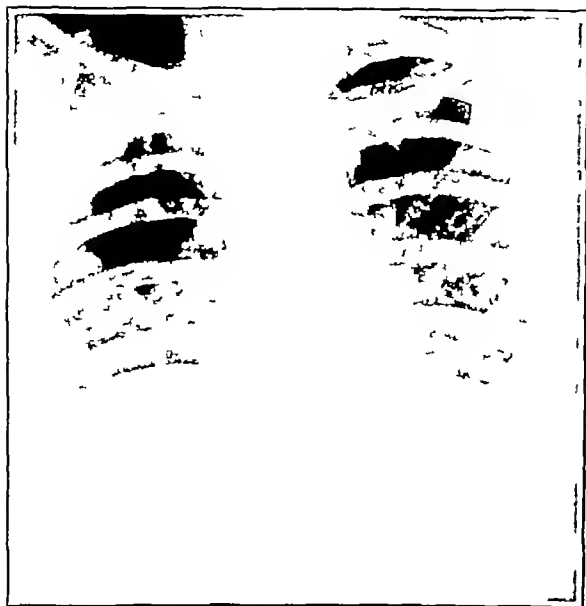

FIGURE 5 Case 2

*X-ray film after bronchoscopic treatment showing relatively good aeration of the right upper lobe*

stenosis is impossible. That such an attitude is unduly pessimistic has been shown by the results in the cases cited above. Samson<sup>6</sup> is quite optimistic in this regard, stating that "localized stenoses

of the stem bronchi can be successfully and repeatedly dilated bronchoscopically" and that "there is often complete remission from wheezing and rhonchi, and from fever due to retained sputum." Samson's opinion is thus in line with our own experience. It should be emphasized that repeated bronchoscopic dilatation may be necessary to secure and maintain an adequate lumen through the area of stenosis. In certain cases, however, as in Case 2, two bronchoscopic treatments have apparently been sufficient. The general rehabilitation of these patients, together with the relief of symptoms, has been noteworthy.

## SUMMARY

Three cases of the stenotic type of tuberculous bronchitis following thoracoplasty are reported. Marked benefit was noted in all 3 cases after bronchoscopic dilatation. In no case did the bronchoscopy reactivate the tuberculosis.

The importance of performing diagnostic bronchoscopy before the institution of collapse therapy is emphasized.

## DISCUSSION

The scarcity of reports of Marfan's syndrome or arachnodactyly in American literature shows how rare this disease must be. It is perhaps better known to the ophthalmologist because of the high percentage of ocular abnormalities. The disease, however, presents features which are of interest to the internist, pediatrician and orthopedist. Although in many cases the various anomalies can be detected at birth, very often they are first picked up during the course of some intercurrent disease. The lack of subcutaneous fat, poor muscular development, large skull and asymmetric thorax all suggest a feeding problem or a vitamin-deficiency disease and mask the true condition. The deformities of the spine and sternum predispose patients to respiratory infections and pulmonary disorders<sup>12</sup> and the general lack of resistance makes them subject to rheumatic infections.<sup>12, 15</sup> As a result these cases show a high infant mortality and a high morbidity for respiratory diseases, with pneumonia as the commonest cause of death. However, the disease in no way interferes with fertility, and in many cases the life span is not materially affected.

In the case just reported, the patient and her family lend support to the theory of the hereditary and congenital character of this condition. In addition, the presence of hemivertebrae in the lower thoracic spine suggests still another theory as to the etiology, recently advanced by Passow,<sup>16</sup>

who maintains that this is a hereditary neurologic disease, with faulty closure of the neural tube, leading to a low-grade, non-progressive syringomelia.

## SUMMARY

There is presented a typical case of Marfan's syndrome or arachnodactyly embodying all the abnormalities of the disease except the major ocular defects. Evidence of the hereditary and congenital character of this condition is supplied.

## THE DETERMINATION OF SERUM PHOSPHATASE AND ITS CLINICAL SIGNIFICANCE\*

JOSEPH M. LOONEY, M.D.†

WORCESTER, MASSACHUSETTS

THE determination of serum phosphatase is one of the more recent laboratory procedures which merits the serious consideration of the clinician. Despite the fact that the test yields valuable information for the pediatrician, the orthopedic surgeon, the internist and even the obstetrician, it has been adopted in relatively few general hospitals. This paper presents a brief report of the method and values obtained in various conditions.

Phosphatase is an enzyme which is able to hydrolyze primary phosphoric acid esters very rapidly at body temperature and has an optimum activity at pH 8.6. The enzyme is found in the

blood and bile, and also in various tissues such as intestinal mucosa, liver, kidney and ossifying cartilage. The enzyme plays an important role in the metabolism of carbohydrate, where it acts in the presence of magnesium in the phosphorylation and hydrolysis of hexose phosphates and glycerophosphates.

The results of the determination are usually expressed in units either according to the method of Kay<sup>1, 2</sup> or that of Bodansky.<sup>3, 4</sup> The unit of Kay is given as the amount of phosphatase in 1 cc of serum that will liberate 1 mg. of phosphorus from sodium  $\beta$ -glycerophosphate at a pH of 7.6 in forty-eight hours at a temperature of 38°C. According to this method serum from a normal adult contains 0.10 to 0.21 unit, while children have a higher value, 0.17 to 0.34 unit. The method of

†Director of Laboratories (Memorial Foundation for Neuro-Endocrine Research), Worcester State Hospital.

cephalic, with prominent frontal bosses. The hair was blond, straight, coarse and abundant. The pupils reacted sluggishly to light but reacted well to mydriatics, and the eyes were normal in all other respects with the exception of deep physiologic cupping of the disks. The external ears were prominent and the superior aspect of each helix was thin, with rudimentary convolutions. The palate was highly arched, and the teeth were irregular, uneven and poorly developed. There was a marked pigeon breast (Fig 1), with asymmetry of the sternum, and a marked left scoliokyphosis of the thoracic spine. The heart was not enlarged, the rate and rhythm were normal and there were no signs of cardiac insufficiency. However, there was a prominent thrill in the 3rd left intercostal space, with a harsh, rumbling, prolonged murmur pervading all of systole and part of diastole, and transmitted all over the precordium. The lungs and abdomen were negative except for a tendency to a pot belly. The limbs were particularly interesting. The bones were elongated but thin. There was practically no subcutaneous fat and the musculature was very poorly developed. The fingers and toes were long and slender (Fig 2), with prominent clubbing and cyanosis of the nails. The

FIGURE 2 Plantar Surface of the Feet

*Note the marked elongation with narrowing of the arch*

fingers were held flexed in the shape of a claw and could not be completely extended. There was a suggestion of acrocyanosis. No muscular palsies and no abnormal neurologic signs were present.

The blood count and urinalysis were normal. A 1:1000 tuberculin test was negative. Wassermann, Kahn and Hinton tests were negative. X-ray films showed thinning and elongation of the long bones, metacarpals, metatarsals and phalanges (Fig 3). The spine showed hemivertebrae in the lower thoracic region, while the skull was essentially negative.

Both the maternal and paternal grandparents were normal and died of natural causes at an elderly age. The father was found to be normal in all respects. The mother, however, the youngest of eight children, presented the same anomalies of her hands and feet as did the patient: the fingers and toes were long and slender and were contracted in claw fashion. Her feet were so long that in spite of the contractures of the toes she was forced to wear a size-8½ shoe. She stated that she had always had a heart murmur. Furthermore, before her marriage she was very thin and undernourished, weighing only 85 pounds. Her second youngest child, an 8-year-old boy, also had the characteristic hands and feet of arachno-

dactyly. The mother's oldest brother had long fingers with large hands and feet and a dorsal scoliokyphosis, and one niece had long fingers and toes, a pigeon breast and

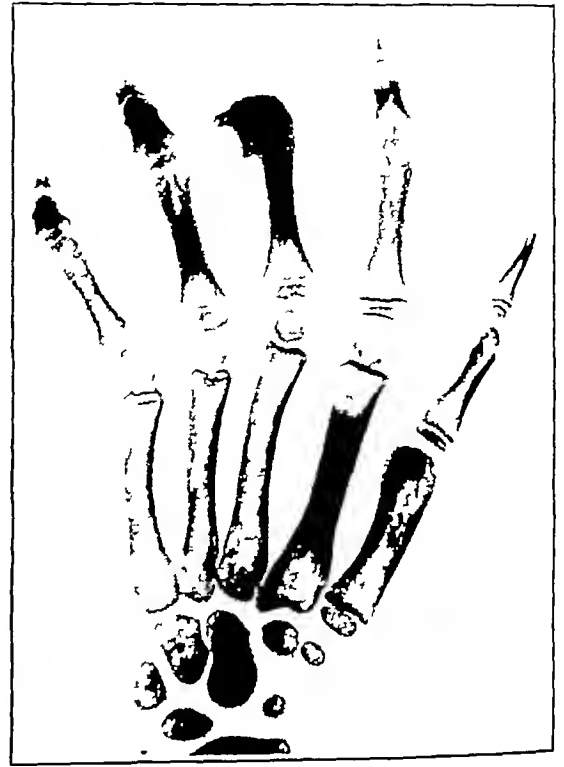

FIGURE 3 X-ray of Left Hand

*The elongation and thinning of the metacarpals and phalanges and the tendency toward a claw hand are clearly shown*

a marked relaxation of ligaments, allowing her to perform acrobatic feats.

Thus, in the family there are no less than 5 cases of varying degrees of arachnodactyly. From the family tree, traced in Figure 4, it is obvious that the maldevelopment in this particular family was inherited from the

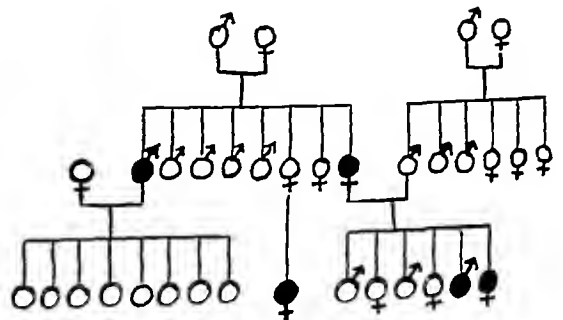

FIGURE 4 Family Tree

*The blackened circles represent individuals with arachnodactyly*

mother by both male and female children. Furthermore, this tendency toward mesodermal abnormalities seems to be a recessive Mendelian characteristic, which can skip one generation only to appear in the second.

diately on the giving of adequate vitamin D therapy, but that the values remain somewhat elevated so long as healing is taking place, and become normal only when the condition is completely cured

In hyperparathyroidism, the elevated values drop to normal after successful operation. Failure of the serum phosphatase to return to normal after operation is therefore an indication that some hyperfunctioning parathyroid tissue has escaped removal. The determination thus becomes a valuable aid to the surgeon.

In primary or metastatic bone cancer the values are usually increased two to five times, up to from 8 to 25 Bodansky units. Bodansky and Jaffe<sup>5</sup> found their highest value of 45.5 units in an osteoplastic type of metastatic bone tumor arising from a carcinoma of the prostate. The osteogenic sarcomas give rise to increased phosphatase values if of the osteoblastic type (Woodard, Twombly and Coley<sup>8</sup>), but not in the osteolytic type. Normal or but slightly elevated values are obtained in chondrosarcoma, giant-cell tumor and multiple myeloma. In the last condition high values for serum calcium and serum protein are frequently found, while the phosphorus values are normal. Slight elevations in the phosphatase levels, up to from 8 to 15 Bodansky units, are found in syphilitic periostitis, osteomalacia and acromegaly. The calcium and phosphorus values are normal in all these conditions except osteomalacia, in which there is a tendency for both substances to be slightly decreased.

The phosphatase values are normal in bone infections, senile osteoporosis, osteogenesis imperfecta and chronic osteitis.

In jaundice the blood serum values are high, this has been shown by Thannhauser and his associates<sup>10</sup> to be due to an activation of the phosphatase present in the serum by some co-factor present in bile. The test has been proposed by Roberts<sup>11</sup> as a means of distinguishing between obstructive jaundice and hepatocellular jaundice. Its value has been denied by Greene, Shattuck and Kaplowitz<sup>12</sup> and by Cantarow and Nelson<sup>13</sup>. On the other hand, Rothman, Meranze and Meranze<sup>14</sup> think that it is of distinct value since the serum phosphatase levels increase in proportion to the bilirubin content in obstructive jaundice but not in other conditions. A similar view is held by Flood, Gutman and Gutman,<sup>15</sup> who state that obstructive jaundice cannot be present if the serum phosphatase is low. It would appear, therefore, that although the procedure does not give a clear-cut differentiation when the values are moderately increased, one can expect that jaundice in the presence of low values rules out the pos-

sibility of obstruction and that extremely high values favor this diagnosis.

In pulmonary tuberculosis with extensive fibrosis and calcification the values may be elevated about 50 per cent above normal. In advanced pulmonary tuberculosis and extensive miliary tuberculosis, on the contrary, low values may occur. A fall in phosphatase values during the course of the disease indicates a grave prognosis, while an elevation is regarded as a favorable sign. An elevation in serum phosphatase has been reported by Meranze, Meranze and Rothman<sup>16</sup> to take place after the sixth month of pregnancy. They state that this increase coincides with the period of marked ossification in the fetus. A failure of the phosphatase to become elevated might therefore be expected in conditions where the bony development of the fetus was interfered with. No evidence substantiating this view has as yet been produced.

The test is also of value to physicians who serve on local boards of health, as a means of detecting the inadequate or improper pasteurization of milk. The enzyme which is present in the mammary gland is excreted in the milk, and is active when the milk is raw. During proper pasteurization the phosphatase is inactivated. If raw milk is added to a solution of sodium phenyl phosphate in a borate sodium hydroxide buffer and incubated for one hour at 37°C there will be a liberation of phenol, which can be detected by the color produced on the addition of 2, 6-dibromoquinone-chloroamide. If proper pasteurization has been carried out the test is negative. If as little as 0.1 per cent of raw milk is added to the pasteurized milk, sufficient hydrolysis of the phenyl phosphate occurs to give a positive test. This amount of enzyme will escape inactivation if the temperature has been held only 1°F below the required one of 143°F, or if the time of holding at the proper temperature has been shortened by five minutes.

A wider use of this test in clinical laboratories seems to be indicated.

#### SUMMARY

The results of serum phosphatase determinations in various clinical conditions are discussed. The test is a valuable adjunct to diagnosis and prognosis in various bone conditions, especially rickets, Paget's disease and osteitis fibrosa cystica. In internal medicine its use in the study of jaundice seems indicated.

Bodansky is more widely used in this country and gives for a unit the amount of phosphatase in 100 cc of serum that will liberate 1 mg of phosphorus from sodium  $\beta$ -glycerophosphate at a pH of 8.9 in one hour at 37°C when no more than 10 per cent of the substrate has been used up. The values obtained by Bodansky's method are higher than those of Kay, the normal adult having 3 to 5 units and the growing child 5 to 12 units.

The method of Bodansky consists of incubating 1 cc of serum with 10 cc of a solution containing 0.5 per cent of sodium  $\beta$ -glycerophosphate and 0.42 per cent of monosodium diethyl barbiturate (Merck's barbitol sodium) at 37°C for one hour. The mixture is then removed and immediately cooled in ice water, and 9 cc of 10 per cent trichloroacetic acid is added. The precipitated proteins are filtered off and the total inorganic phosphorus determined in 5 cc of the filtrate, or in an aliquot made up to 5 cc with water, by adding 4 cc of 1.87 per cent sodium molybdate in 10 N sulfuric acid and 1 cc of freshly prepared 0.3 per cent stannous chloride. The blue solution thus obtained is compared in a colorimeter with a potassium acid phosphate standard containing 0.02 mg of phosphorus which has been similarly treated. For more detailed information and the precautions to be observed, the original papers of Bodansky<sup>3, 4</sup> should be consulted.

High concentrations of phosphatase are found in ossifying cartilage, while only traces are found in non-ossifying cartilage. This has been shown to be due to the phosphatase content of the osteoblastic cells, and the amount of phosphatase is roughly proportional to the bone-forming activity. The phosphatase of the intestinal mucosa is concerned with the splitting of phosphoric esters preparatory to their absorption, that in the kidney is concerned with elimination. In bone formation it is thought that the enzyme acts to form locally a high concentration of phosphate by splitting of glycerophosphate, and thus causes precipitation of calcium phosphate.

In healing fractures, Bodansky and Jaffe<sup>5</sup> reported a slight increase of phosphatase in 4 of 13 adults. Botterell and King<sup>6</sup> made determinations of the phosphatase content of the callus and blood serum of rabbits that had sustained experimental fractures of the radius. They found that there was an increase in the phosphatase of the callus amounting to from three to six times that of the normal bone from the other leg. No increase was noted in the phosphatase content of the serum of the rabbits following fractures of one or both radius. Similar results were obtained by Wilkins and Regen,<sup>7</sup> who found an increase of phosphatase

at the site of the injury, which reached a maximum about the twenty-second day and then declined. The evidence would therefore indicate that no significant change in serum levels of phosphatase occurs during the healing of fractures.

In the table the values for serum phosphatase found in various clinical entities are recorded, together with the levels of calcium and phosphorus usually associated with them.

*Serum Phosphatase Phosphorus and Calcium in Normal and Pathologic Conditions*

DIAGNOSIS	SERUM PHOSPHATASE	SERUM PHOSPHORUS	SERUM CALCIUM

Tuberculosis with extensive fibrosis	4-6	4	10
Pregnancy	6-23	3	10-12

In conditions affecting bone, the highest values are obtained when there is marked bone activity, either in the formation of new bone or the destruction of old bone. Thus we find that in osteitis deformans (Paget's disease), hyperparathyroidism (osteitis fibrosa cystica) and rickets the phosphatase levels may be increased ten to twenty times above the normal values. However, in osteitis deformans the calcium and phosphorus values are normal, while in hyperparathyroidism the calcium is elevated and the phosphorus is low, and in rickets both calcium and phosphorus are low. The severity of the condition in all three diseases is indicated by the extent to which the serum phosphatase is elevated.

In rickets the level of the serum phosphatase gives the most reliable single index for evaluating early and doubtful cases. Barnes and Carpenter<sup>8</sup> found that while only 26.7 per cent of 187 cases clinically diagnosed as rickets were detected by x-ray and only 19.8 per cent by low phosphorus values, 65.8 per cent had serum phosphatase values above 12.5 units, which is taken as the upper limit of normality. On giving 800 Steenbock units of vitamin D daily they found an average drop in phosphatase from 58.3 to 12.7 units in three months. It has been shown that initially high values of phosphatase in active rickets begin to drop imme-

diately on the giving of adequate vitamin D therapy, but that the values remain somewhat elevated so long as healing is taking place, and become normal only when the condition is completely cured

In hyperparathyroidism, the elevated values drop to normal after successful operation. Failure of the serum phosphatase to return to normal after operation is therefore an indication that some hyperfunctioning parathyroid tissue has escaped removal. The determination thus becomes a valuable aid to the surgeon.

In primary or metastatic bone cancer the values are usually increased two to five times, up to from 8 to 25 Bodansky units. Bodansky and Jaffe<sup>7</sup> found their highest value of 45.5 units in an osteoplastic type of metastatic bone tumor arising from a carcinoma of the prostate. The osteogenic sarcomas give rise to increased phosphatase values if of the osteoblastic type (Woodard, Twombly and Coley<sup>8</sup>), but not in the osteolytic type. Normal or but slightly elevated values are obtained in chondrosarcoma, giant-cell tumor and multiple myeloma. In the last condition high values for serum calcium and serum protein are frequently found, while the phosphorus values are normal. Slight elevations in the phosphatase levels, up to from 8 to 15 Bodansky units, are found in syphilitic periostitis, osteomalacia and acromegaly. The calcium and phosphorus values are normal in all these conditions except osteomalacia, in which there is a tendency for both substances to be slightly decreased.

The phosphatase values are normal in bone infections, senile osteoporosis, osteogenesis imperfecta and chronic osteitis.

In jaundice the blood serum values are high, this has been shown by Thannhauser and his associates<sup>10</sup> to be due to an activation of the phosphatase present in the serum by some co-factor present in bile. The test has been proposed by Roberts<sup>11</sup> as a means of distinguishing between obstructive jaundice and hepatocellular jaundice. Its value has been denied by Greene, Shattuck and Kaplowitz<sup>12</sup> and by Cantarow and Nelson.<sup>13</sup> On the other hand, Rothman, Meranze and Meranze<sup>14</sup> think that it is of distinct value since the serum phosphatase levels increase in proportion to the bilirubin content in obstructive jaundice but not in other conditions. A similar view is held by Flood, Gutman and Gutman,<sup>15</sup> who state that obstructive jaundice cannot be present if the serum phosphatase is low. It would appear, therefore, that although the procedure does not give a clear-cut differentiation when the values are moderately increased, one can expect that jaundice in the presence of low values rules out the pos-

sibility of obstruction and that extremely high values favor this diagnosis.

In pulmonary tuberculosis with extensive fibrosis and calcification the values may be elevated about 50 per cent above normal. In advanced pulmonary tuberculosis and extensive miliary tuberculosis, on the contrary, low values may occur. A fall in phosphatase values during the course of the disease indicates a grave prognosis, while an elevation is regarded as a favorable sign. An elevation in serum phosphatase has been reported by Meranze, Meranze and Rothman<sup>16</sup> to take place after the sixth month of pregnancy. They state that this increase coincides with the period of marked ossification in the fetus. A failure of the phosphatase to become elevated might therefore be expected in conditions where the bony development of the fetus was interfered with. No evidence substantiating this view has as yet been produced.

The test is also of value to physicians who serve on local boards of health, as a means of detecting the inadequate or improper pasteurization of milk. The enzyme which is present in the mammary gland is excreted in the milk, and is active when the milk is raw. During proper pasteurization the phosphatase is inactivated. If raw milk is added to a solution of sodium phenyl phosphate in a borate sodium hydroxide buffer and incubated for one hour at 37°C there will be a liberation of phenol, which can be detected by the color produced on the addition of 2, 6-dibromoquinone-chloroamide. If proper pasteurization has been carried out the test is negative. If as little as 0.1 per cent of raw milk is added to the pasteurized milk, sufficient hydrolysis of the phenyl phosphate occurs to give a positive test. This amount of enzyme will escape inactivation if the temperature has been held only 1°F below the required one of 143°F, or if the time of holding at the proper temperature has been shortened by five minutes.

A wider use of this test in clinical laboratories seems to be indicated.

#### SUMMARY

In internal medicine its use in the study of jaundice seems indicated.

## PULMONARY MONILIASIS\*

JOHN J. DECKER, M.D.†

BOSTON

**B**RONCHOMONILIASIS may occur alone or in association with tuberculosis or other chronic pulmonary disease. The causative agent, a monilia, is a fungus widely distributed in nature, usually in the saprophytic form. It is present on dead leaves and decomposed wood, and in man and animals is often found on the skin and mucous membranes. Under certain conditions its role may change from the saprophytic to the parasitic form, and it then produces cutaneous, bone, visceral, mucous membrane or pulmonary lesions. In 6 of 178 consecutive cases of pulmonary infections Keiper<sup>1</sup> isolated moniliae in the sputum, and this organism was proved to be the cause of the infection in each case, on the other hand moniliae were found in only 3 throat cultures from 100 normal individuals, none of whom had signs or symptoms of infection. Bronchomoniliasis is no longer rare, according to Ikeda,<sup>2</sup> but the diagnosis must be made with extreme caution, because the organism is found frequently in sputum and secretions from the upper respiratory tract in normal individuals and particularly in patients suffering from chronic pulmonary infections, especially pulmonary tuberculosis and carcinoma.

Bakst, Hazard, and Foley<sup>3</sup> and Davis and Warren<sup>4</sup> have reviewed the literature and classified the pulmonary disease into three types.

The mild type, which may not affect the general health of the individual to any great extent. There is a cough with mucopurulent sputum, and usually no hemoptysis or fever. Physical examination of the chest may reveal scattered fine rales. The condition may persist for several months or may progress to a more severe form.

The intermediate type, which may simulate either bron-

chitis or early pulmonary tuberculosis. Fever, cough, mucopurulent sputum, occasionally blood streaked sputum, dyspnea, and localized or generalized fine or coarse rales are frequently observed.

The severe type, in which the history and physical signs are very similar to those of well advanced pulmonary tuberculosis. General malaise, loss of weight, dyspnea, fever and cough are usually present, and often blood streaked sputum, chest pains, rales and signs of pleural thickening and consolidation.

The outcome in the last group of cases is frequently fatal. Stovall and Greeley<sup>5</sup> point out that the striking thing about most of these cases is the disproportion between the symptoms and the pathologic changes. The patient usually has only a moderately severe cough, and but little sputum, which is mucopurulent rather than purulent, and may be blood-tinged. Fever, if any, is of a low grade, and the leukocyte count is essentially normal. There is frequently a history of pneumonia or influenza, and some patients have had asthma for several years.

Black and Eddy<sup>6</sup> reported a case involving the lungs, skin, subcutaneous tissue and bones which had previously been studied, and in which diagnoses of syphilis, tuberculosis and leprosy were suspected before the final diagnosis of moniliasis was made and confirmed by laboratory study. Jones and Martin<sup>7</sup> report the finding of yeastlike organisms in the vaginal tracts of 52 pregnant and 16 non-pregnant women. *Monilia albicans* was found in 19 of these cases. Fawcitt<sup>8</sup> studied a group of cases of pulmonary moniliasis in conjunction with his work in pneumoconiosis. He found pulmonary mycoses in various types of farm and dairy workers, and distinguished these infections clinically from pneumoconiosis by the occupational history, roentgen-ray findings, and mode

\*From the Lakeville State Sanatorium, Middleboro, Massachusetts.

†Surgical intern, Carney Hospital, Boston, formerly assistant superintendent, Lakeville State Sanatorium, Middleboro, Massachusetts.

of onset, which is acute in bronchomycosis, and gradual, with a history of long exposure to silica, in pneumoconiosis

It is evident that the pathologic conditions due to monilia present numerous problems in diagnosis. The finding of budding yeast cells and mycelia in any of the routine stains or cultures should aid in the diagnosis. Yeast cells are generally found in the original smears, stained by any of the usual methods, before further bacteriological study has been attempted. In order to classify the organism, however, its cultural characteristics must be studied. Davis and Warren<sup>4</sup> have described a simple method for the study of broth culture in unstained preparations. Martin et al<sup>9</sup> published a classification of the various forms of monilia.

In the following case, yeast cells were found by our pathologist, Dr Alvin O Severance, in all the direct smears of sputum. Methylene blue, Gram and acid-fast stains were equally efficient in revealing budding cells and mycelia, whether the smears were made directly from sputum or from culture media. A culture of the organism was studied by Dr Donald S Martin, of Duke University School of Medicine, and was classified by him, through cultural characteristics, as *Monilia albicans*.

#### CASE REPORT

A 57 year-old farm worker was seen September 27, 1935, with a chief complaint of weakness. He stated that he was perfectly well until 1 week before entry, when he developed a cold with cough but no sputum. He then became progressively weaker, and developed dyspnea on slight exertion, and anorexia. His usual work became more difficult to accomplish, and just prior to entry he was unable to do any work whatsoever due to marked fatigue. There were no other complaints. The past history was essentially negative, except for a fracture of the 10th left rib 9 months previously, at which time a roentgenogram had been taken (Fig 1).

Physical examination revealed a very well-developed, well nourished man, who appeared weak and definitely ill. The nose and throat were normal. The lungs were clear. Tactile and vocal fremitus and breath sounds were within normal limits, and no rales were heard either before or after cough. The heart was normal. The blood pressure was 140/85. Abdominal and rectal examinations were negative. The temperature was 101°F. The white-cell count was 8850, with a normal differential. Urinalysis was entirely normal.

Bed rest and treatment for upper respiratory infection were started. The temperature remained elevated, the cough continued without sputum and the physical examination was unchanged until the 3rd day after admission, when examination of the chest revealed diminished tactile fremitus over the left midchest and base posteriorly, with diminished breath sounds and fine rales in this region. The findings were suggestive of a pneumonic process, and a roentgen ray examination revealed obliteration of both diaphragm shadows. The lung markings were increased at both bases, there was haziness in the left lower lobe, and

a dense shadow filled the right base, the upper border of which was markedly irregular in outline. There was also a moderately dense, enlarged right hilus shadow (Fig 2). After viewing the roentgenogram, examination of the chest was repeated, but no rales could be heard on the right side. On the following day (the 4th after admission), however, fine rales were heard over the right base

FIGURE 1

*This roentgenogram, taken December 7 1934 when the patient had a fracture of the tenth left rib shows moderate thickening of the bronchial tree with no evidence of pulmonary infiltration. There is a suggestion of calcification in the shadows in the hilus especially those on the right side.*

as well as the left, and over the left midlung field posteriorly. The patient raised a small amount of thick, brown, tenacious sputum, which was smeared and cultured. No acid fast bacilli were seen, but in all smears there were many yeast cells. Suspecting that the yeast was a contaminant, we instructed the patient to wash his mouth and throat well with saline solution, after which another sputum specimen was obtained, similar to the first. Yeast cells were found in all the stained smears of this specimen. Because of the similarity of these organisms to moniliae, the patient was given potassium iodide, 15 gr three times daily. The lung findings remained essentially unchanged, the cough continued and the sputum increased, with a larger number of budding cells and mycelia in each subsequent specimen until the 10th day, when the temperature, which had gradually subsided, had become normal. A roentgen film of the chest on this day showed calcification at the line of fracture of the 10th left rib posteriorly. The cardiac borders were indistinct in outline and merged with moderately dense hilar and perihilar shadows. Peribronchial thickening and fine mottling was evident in the right lung, extending toward the base. The lower two thirds of the left lung field was mottled, and there were dense, confluent patches throughout this area. There was a faint outline of a large node in the right hilus, and a dense shadow in the left hilus consistent with a calcified node.

The patient began to improve clinically. His appetite increased, the cough and sputum decreased, physical examination showed diminution of abnormal lung findings, and on the 17th day was negative except for fine rales in

FIGURE 2

*This film, taken on September 30 1935 three days after admission, when the first signs of pulmonary disease were detected clinically reveals dense shadows in both bases, which have obliterated the diaphragm, marked infiltration in the periphery, especially on the left, both apices clear, and definite calcification of the lymph nodes of the hili, more marked on the right*

both bases. Roentgenograms taken this day showed the right border of the heart more distinctly. The hilar shadow on the right was less dense. Both diaphragm shadows were seen, the left being clearer than the right. There was a minimum of haziness in the right costophrenic angle. Peribronchial thickening was unchanged at the right base. More diffuse mottling and peribronchial thickening were seen in the left base, with loss of the larger conglomerate patches. The cough continued to subside and the sputum became increasingly less until the 24th day following admission, when the sputum showed only one colony of yeast cells on culture. Roentgen films at this time showed the right diaphragm more distinctly than theretofore, and a clear costophrenic angle and slightly diminished peribronchial thickening. The mottling in the left lung field was more diffuse, with a considerable amount of beading along the peribronchial vessels. The patient's activity was gradually increased after the 25th day, and by the 31st day he felt perfectly well and had no fatigue following moderate exercise, while examination revealed only an occasional fine rale in either base, and a roentgenogram showed the heart and diaphragm shadows more distinctly. The peribronchial thickening and mottling had diminished, and there were very few residual pathologic findings.

The patient was discharged on the 31st day (October 28), and returned to work December 3. Roentgen films of the chest taken then and December 26 showed an increase in pulmonary markings in both bases.

There was no apparent variation in the peribronchial thickening when the roentgen film taken December 7, 1934 (Fig 1), was compared with the follow-up roentgenogram taken April 9, 1937 (Fig 3). The latter, however, showed the calcified hilar nodes more distinctly. There has been no evidence of recurrence.

Bakst et al.<sup>3</sup> describe a very acute form of pulmonary moniliasis which may have a sudden onset with rapid progression to a fatal termination. The case reported here may be classified in this group because of the sudden onset and the rapid progression, but it is unique in that it terminated in complete recovery in a relatively short time. In any unusual type of pulmonary lesion the possibility of moniliasis must be considered, and appropriate therapy instituted if this condition be found.

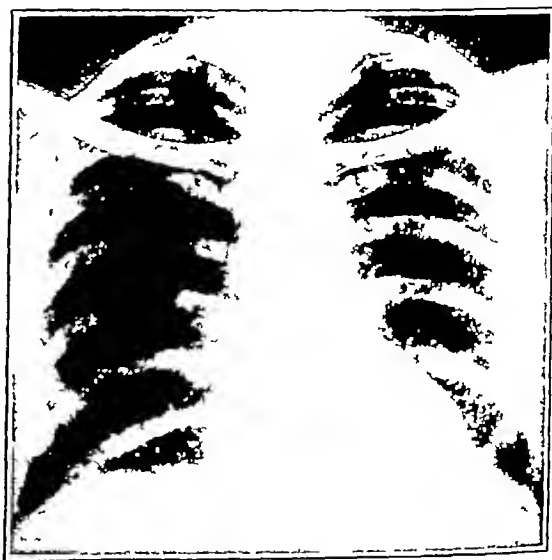

FIGURE 3

*This roentgen film, taken for follow up on April 9, 1937, shows the periphery clear, the bronchial tree not increased in density (compare with Fig 2) and calcification in the hili*

## REPORT ON MEDICAL PROGRESS

## TUMORS OF BONE

CHANNING C. SIMMONS, M.D.\*

BOSTON

UNTIL Ewing suggested the term "osteogenic tumor," which has now been generally adopted, the nomenclature of the primary bone tumors was confusing. The embryonic fibroblast is assumed to be the cell of origin of all these tumors, and this cell is capable of developing into any form of mesoblastic tissue—relatively adult fibrous tissue, cartilage or bone. Many or all these tissues are usually found in a primary bone tumor, although usually one predominates. The terms fibro-, chondro-, osteo- or anaplastic may be used as prefixes or adjectives to designate the predominating type.

In 1921 the committee of the Registry of Bone Sarcoma of the American College of Surgeons, together with a committee from the American Association of Pathologists and Bacteriologists, formulated a classification based on the above premise. This has since been generally adopted in this country, and with slight modifications will be followed in this article. It leaves much to be desired but is the most comprehensive yet suggested. Reticulum-cell sarcoma and liposarcoma have been added, for they have been recognized as entities by the committee.

In 1931 Geschickter and Copeland<sup>1</sup> published a book in which they advocated a radically different classification, presumably based on embryology. It is impossible to reconcile their classification with that of the registry, which does not attempt to postulate the highly doubtful embryologic stages at which bone tumors may arise. Several pathologists have also suggested classifications which, however, are somewhat confusing to the clinician.

The Registry classification of bone tumors is as follows:

## Tumors originating in bone

## Osteogenic tumors

Benign osteoma, chondroma, etc.

Malignant (osteogenic sarcoma) periosteal, sclerosing, chondral, etc.

Ewing's sarcoma

Reticulum-cell sarcoma

Liposarcoma

Myeloma (plasma-cell tumor)

Unclassified malignant tumors

Benign giant-cell tumor

Angioma

## Other bone tumors

Metastatic tumors cancer, hypernephroma, lymphoma, etc.

Parosteal fibrosarcoma

Odontoma, etc.

Other conditions subperiosteal hematoma, bone cyst, osteitis fibrosa cystica, Paget's disease, sarcoid, xanthoma, etc.

## BENIGN OSTEOGENIC TUMORS

The non-malignant osteogenic tumors are composed of nearly normal bone, cartilage and fibrous tissue in varying amounts. A common seat for these tumors is about the joints or beneath the fingernails or toenails. When cartilage predominates there is always a possibility of malignant change, and these tumors should be completely removed by surgery. An osteoma should be removed when it is in an accessible situation or causing symptoms, for the borderline between benign and malignant tumors cannot be ascertained.

Multiple exostosis is a congenital condition in which such osteocartilaginous tumors occur near the epiphyseal lines in a few or many bones. Rarely one or more of these become malignant.

## MALIGNANT OSTEOGENIC TUMORS (SARCOMAS)

Sarcoma of the bone is a particularly malignant tumor, but the degree of malignancy and the prognosis following treatment have been shown to depend to a large extent on the amount of differentiation of the cells in the major portion of the growth (Meyerdig, <sup>3</sup> Simmons<sup>2</sup>). Thus tumors composed chiefly of cartilage, bone or fibrous tissue have a better prognosis than those composed chiefly of undifferentiated cells. The malignancy also varies somewhat according to the location. In the jaw or flat bones the tumor runs a somewhat different course than is the case in a long bone. Tumors of the phalanges of the fingers or toes rarely cause metastases, even though the histology suggests malignancy. The undifferentiated anaplastic form is the common type seen in children.

Osteogenic tumors usually arise in the epiphyseal ends of the long bones, and in most cases are both subperiosteal and medullary, as well as osteolytic and osteoblastic. They are composed of all types of mesoblastic tissue in varying proportions, and the prefixes osteo-, chondro-, myxo-, and so forth, are used as adjectives to describe the predominating tissue. Metastases commonly take place

through the blood stream and are usually found in the lungs. A form of low malignancy, composed chiefly of fibrous tissue and confined to the medulla, is recognized.

The first symptom of osteogenic sarcoma is usually pain in a bone, not relieved by rest and often referred to the adjacent joint. The tumor becomes demonstrable after a varying period depending on the point of origin, that is, whether medullary or periosteal. The late symptoms are well known. The importance of trauma as an etiologic factor is disputed, but a history of a recent injury to the part is often obtained.

The radiograph ordinarily shows a tumor at the end of a long bone, the appearance varying somewhat according to the situation, that is, whether chiefly subperiosteal or central, and also according to whether the tumor is osteolytic or osteoblastic. In very early cases the film may be negative, but by the time the symptoms are sufficiently pronounced for the patient to seek medical advice, bone changes are usually evident. There are always bone destruction and bone formation in varying amounts. The periosteum may be pushed up with ray formation beneath it, and the so-called "reactive triangle," where the periosteum joins the shaft at the upper end of the growth, is often seen. When the tumor has attained considerable size the shadow of the shaft is faintly seen through it. In the film the rare, central, fibrous type closely resembles a giant-cell tumor and may be confused with it.

The symptoms, history and physical examination, as well as the radiograph, should all be considered in arriving at a diagnosis for many atypical films are seen. Chemical analysis of the blood is at times of aid in making a diagnosis (Table 1), but the findings should be care-

lung metastases within three years is the usual story. Tumors composed of relatively adult tissue permit a comparatively good prognosis. Lung metastases developing five or more years after removal of the primary growth are occasionally seen. The experience of surgeons whose practice is limited to children is most pessimistic. Simmons<sup>2</sup> in a small series of consecutive cases reports 39 per cent five-year cures, and Meyerding<sup>3</sup> in a larger series 23 per cent.

Amputation through the bone next proximal to that diseased or disarticulation is the treatment of choice. It is generally agreed that the tumors are radio-resistant. In the Registry of Bone Sarcoma there are 101 five-year cures following surgery and 1 following radiation treatment, but in the latter case the diagnosis was not confirmed by biopsy. The operation should not be done if there is evidence of remote metastases, except for the relief of pain, which at times may be controlled by radiation or chordotomy. The treatment by the mixed toxins of streptococcus and *Bacillus prodigiosus* (Coley's serum) has been advocated, but proof of its efficacy has not been supplied. B. L. Coley<sup>4</sup> employs it only in endothelial myeloma and in conjunction with surgery in the hope of destroying microscopic foci in the lungs. Brunswick<sup>5</sup> found that experimentally it had no effect on animal tumors but concluded "It has not been proved at present to be totally ineffective in all cases."

#### EWING'S SARCOMA

Ewing's sarcoma, or endothelial myeloma, is probably the small round-cell sarcoma mentioned by earlier writers. It usually arises in the shaft of a long bone or in the flat bones, and is charac-

TABLE 1 *Blood Constituents in Cases with Bone Tumors*

	OSTEITIS FIBROSA CYSTICA	OSTEOGENIC SARCOMA	EWING'S SARCOMA	GIANT CELL TUMOR	MYELOMA	METASTATIC CANCER	PAGE'S DISEASE
Calcium	Increased	Normal	Normal	Normal	Often increased	Normal	Normal
Phosphorus	Diminished	Normal	Normal	Normal	Normal	Normal	Normal
Phosphatase	Slightly increased	Usually increased	Normal	Normal	Normal	At times slightly increased	Usually high
Serum protein	Normal	Normal	Normal	Normal	Often increased	Normal	Normal
Bence Jones (urine)	Absent	Absent	Absent	Absent	Often present	May be present	Absent

fully interpreted. A biopsy is often necessary for confirmation. This should be done with a tourniquet in place and with permission secured for immediate amputation should the tumor prove malignant. Such permission is often difficult to obtain, and the family grasps any form of treatment, short of sacrificing a limb, that may be of benefit.

The prognosis depends on the type of the tumor, its duration and its situation. Death with

terized by bone destruction with no tumor bone formation, although there is occasionally some reactive new bone.

The early symptoms are pain and swelling, often with remissions. There may be a slight rise of temperature with an elevated white-cell count. In the late stages the temperature may rise to 103°F. Metastases take place to the lungs and to other bones, the skull being a common site.

The chemical constituents of the blood are normal.

The x-ray films show bone destruction, often with a characteristic onion-skin appearance of the periosteum. There may be reactive bone formation. The films are sometimes confused with those of a xanthoma or reticulum-cell sarcoma.

The disease with which it is most commonly confused in the early stage is osteomyelitis, but xanthoma and reticulum-cell sarcoma should always be considered.

The prognosis is bad. The disease may run an acute course, but the average length of survival is two or three years. In 14 of the 236 cases in the Registry of Bone Sarcoma the patients have lived over five years. Thirteen of these 14 cases were treated by surgery, often supplemented by Coley's serum or radiation, and 1, after biopsy, by radiation and Coley's serum only.

The tumor is very radio-sensitive, and following treatment the local growth practically disappears, but metastases occur. Amputation or resection is the treatment of choice. Treatment by Coley's serum has been recommended, and seems to be of greater value in the treatment of this tumor than in that of osteogenic sarcoma.

#### RETICULUM-CELL SARCOMA

Reticulum-cell sarcoma is a tumor usually placed in the group of malignant lymphomas. It has been recognized as occurring in the reticuloendothelial system but recently has been shown to arise in a single bone to which it is apparently limited (Parker and Jackson<sup>6</sup>). The symptoms are similar to those of osteogenic sarcoma. Although the tumor may reach a large size, the general condition of the patient remains excellent and metastasis is slow to occur. The x-ray in the early cases shows central bone destruction. Later a large part of the bone may be destroyed, with some new-bone formation. The prognosis is relatively good even when the tumor has attained a large size. The tumors are radio-sensitive but the therapeutic results are apparently better following radical surgery, although the patient may develop similar tumors in other parts of the reticuloendothelial system many years later.

#### LIPOSARCOMA

Primary liposarcoma of bone described by Stewart<sup>7</sup> is a rare form of tumor derived from the fat cells. Its clinical behavior is similar to that of osteogenic sarcoma.

#### MYELOMA (PLASMA-CELL TUMOR)

This is a tumor of the bone marrow composed of plasma cells. It is usually multiple, chiefly affect-

ing the flat bones, but is occasionally limited to one bone (Cutler, Buschke and Cantril<sup>8</sup>). It is most frequently seen in adult males. The symptoms are pain, tumor and those due to bone deformity. Bence-Jones protein may be present in the urine, and plasma cells in the blood smear. The serum globulin may be increased. None of these findings are constant or to be found in every case. The disease runs a course, unaffected by treatment, of a few months to many years. There is 1 case in the Registry of Bone Sarcoma in which the patient was living and in good health twenty years after the diagnosis had been established by biopsy. The classical x-ray film shows centrally placed multiple areas of bone destruction, but atypical radiographs are common. The treatment is symptomatic and by radiation. The growths are usually radio-resistant, but occasionally respond satisfactorily.

#### BENIGN GIANT-CELL TUMOR

Benign giant-cell tumors arise most commonly in the epiphyseal ends of the long bones. They are not primarily malignant growths, although malignant change apparently occurs after a period of time in about 7 per cent of cases (Simmons,<sup>9</sup> Codman<sup>10</sup> and Stewart<sup>11</sup>). The tumors arise in the medulla and cause bone destruction and distention of the cortex, with no new-bone formation.

The symptoms are pain, tumor and later pathologic fracture. There may be collapse which causes deformity of the adjacent joint.

The x-ray film shows a cavity in the medulla near the joint, with bone destruction and absorption of the cortex, with distention. The cavity may appear to be divided by fine trabeculae. At the lower limits of the growth there is a sharp concavoconvex line of demarkation, above, it is limited by the epiphyseal or joint cartilage. One form is seen in young individuals, usually arising in the greater tuberosity of the humerus or the trochanter or condyle of the femur, which extends across the epiphyseal line. These tumors contain cartilage and may be confused with sarcoma (Codman<sup>12</sup>).

The diagnosis is made on the symptoms and on the radiograph. Bone cysts, the fibrous type of osteogenic sarcoma, angioma and metastatic tumors are the chief conditions with which it may be confused.

The majority of these tumors are non-malignant, and amputation is not indicated except for deformity or where other forms of treatment have failed. The choice of treatment lies between radia-

through the blood stream and are usually found in the lungs. A form of low malignancy, composed chiefly of fibrous tissue and confined to the medulla, is recognized.

The first symptom of osteogenic sarcoma is usually pain in a bone, not relieved by rest and often referred to the adjacent joint. The tumor becomes demonstrable after a varying period depending on the point of origin, that is, whether medullary or periosteal. The late symptoms are well known. The importance of trauma as an etiologic factor is disputed, but a history of a recent injury to the part is often obtained.

The radiograph ordinarily shows a tumor at the end of a long bone, the appearance varying somewhat according to the situation, that is, whether chiefly subperiosteal or central, and also according to whether the tumor is osteolytic or osteoblastic. In very early cases the film may be negative, but by the time the symptoms are sufficiently pronounced for the patient to seek medical advice, bone changes are usually evident. There are always bone destruction and bone formation in varying amounts. The periosteum may be pushed up with ray formation beneath it, and the so-called "reactive triangle," where the periosteum joins the shaft at the upper end of the growth, is often seen. When the tumor has attained considerable size the shadow of the shaft is faintly seen through it. In the film the rare, central, fibrous type closely resembles a giant-cell tumor and may be confused with it.

The symptoms, history and physical examination, as well as the radiograph, should all be considered in arriving at a diagnosis for many atypical films are seen. Chemical analysis of the blood is at times of aid in making a diagnosis (Table 1), but the findings should be care-

fully interpreted. A biopsy is often necessary for confirmation. This should be done with a tourniquet in place and with permission secured for immediate amputation should the tumor prove malignant. Such permission is often difficult to obtain, and the family grasps any form of treatment, short of sacrificing a limb, that may be of benefit.

The prognosis depends on the type of the tumor, its duration and its situation. Death with lung metastases within three years is the usual story. Tumors composed of relatively adult tissue permit a comparatively good prognosis. Lung metastases developing five or more years after removal of the primary growth are occasionally seen. The experience of surgeons whose practice is limited to children is most pessimistic. Simmons<sup>2</sup> in a small series of consecutive cases reports 39 per cent five-year cures, and Meyerding<sup>3</sup> in a larger series 23 per cent.

Ewing's sarcoma

Ewing's sarcoma, or endothelial myeloma, is probably the small round-cell sarcoma mentioned by earlier writers. It usually arises in the shaft of a long bone or in the flat bones, and is charac-

TABLE 1 Blood Constituents in Cases with Bone Tumors

terized by bone destruction with no tumor bone formation, although there is occasionally some reactive new bone.

The early symptoms are pain and swelling, often with remissions. There may be a slight rise of temperature with an elevated white-cell count. In the late stages the temperature may rise to 103°F. Metastases take place to the lungs and to other bones, the skull being a common site.

## CASE 25151

## PRESENTATION OF CASE

*First Admission* A forty-five-year-old, white, married, schoolteacher was admitted complaining of sore throat.

Two days before admission she had a sore throat, chill and backache. Her temperature was 101.8°F. On the following day her blood had a white-cell count of 1000, with no polymorphonuclears, and when repeated showed 750 cells, with no polymorphonuclears. About two years before entry she began having urinary frequency and urgency. Nine months later a small piece of chronically inflamed tissue was fulgurated on the edge of the left ureteral orifice. The bladder healed readily, but the patient complained of the same symptoms throughout the following year. Her physician thought that these complaints were psychogenic. During the two years she had taken Allonal and Peralga quite often, using the former practically every night during the previous three or four months.

Physical examination showed a thin woman with a mottled, purplish complexion. The posterior nasopharynx was acutely inflamed and showed a right linear ulceration. There were a number of large external hemorrhoids.

The blood showed a red-cell count of 5,100,000 with 80 per cent hemoglobin. During the first nine days in the hospital the white-cell count ranged between 1500 and 3400, with polymorphonuclears varying between 0 and 20 per cent. The tenth day she had a white-cell count of 7400 with 55 per cent polymorphonuclears.

She rapidly improved and was discharged on the nineteenth hospital day.

*Second Admission* (three years and three months later) The patient complained of constipation of several years' duration, more recently accompanied by headaches.

Barium enema x-rays showed a large atonic colon. A gastrointestinal x-ray series was negative. Blood and urine examinations were normal. She was discharged on the third hospital day.

*Final Admission* (fifteen months later) Six days before admission she had had a severe head-

ache and a chilly feeling, followed by a temperature of 104°F. Her throat was sore. The next day she felt cold, became nauseated and vomited. Two days later she had pain over the left face and ear, with headache. Her nausea continued. On the morning of the day of admission she was deeply jaundiced. She had taken no drugs except laxatives since her first admission. Nine days before entry she had had injection treatment for hemorrhoids.

Physical examination showed a jaundiced acutely ill woman. The throat was acutely red. The eardrums were negative. Examination of the chest was negative. The liver was not palpable and by percussion was thought to be smaller than normal.

The temperature was 102.5°F., the pulse 115, and the respirations 22.

Examination of the urine showed the presence of a small amount of bile. The blood had a red-cell count of 3,050,000 with 45 per cent hemoglobin, and a white-cell count of 11,400 with 87 per cent polymorphonuclears. There was moderate achromia and variation in size of the red cells, with many of them larger than normal, there was an occasional elongated cell and a rare stippled cell. The platelets were normal. The nonprotein nitrogen of the serum was 19 mg. per 100 cc., the icteric index 50. A stool examination was guaiac positive. A throat culture was negative for hemolytic streptococci but showed *Staphylococcus aureus*. A blood culture was negative at the end of eighteen hours but on the third day showed *Staphylococcus aureus* in both flasks.

X-ray films of the chest were negative. On the second hospital day the icteric index was 70. On the fourth hospital day the patient was much worse, her temperature being 103.5°F., where it had remained for the previous two days. She rapidly failed and died on the sixth hospital day.

## DIFFERENTIAL DIAGNOSIS

DR. CHARLES L. SHORT This patient's first admission can be dismissed in a few words. She evidently had agranulocytosis due to the ingestion of drugs containing amidopyrin since both hypnotics mentioned at that time contained this drug. Recently the manufacturers of Allonal have changed the amidopyrin to acetophenetidin (phenacetin), which rarely, if ever, has caused agranulocytosis. We know that the agranulocytosis is usually primary and that the infection, in this case a nasopharyngitis with ulceration, comes later. The record gives us no information as to whether she recovered spontaneously or following the usual measures used for treating agranulocytosis. The case for the drug etiology of agranulocytosis is

tion and surgery. Good and occasionally poor results have been obtained by both methods.

When the tumor is in an accessible position, such as the upper end of the fibula or the lower end of the ulna, resection is to be advised on account of the possibility of malignant change. In other situations, such as about the knee, a common seat for the tumor, the choice lies between radiation treatment and conservative surgery, that is, curetting, and excision of the entire tumor. The resulting defect does not entirely fill in with new bone, and if it is filled with bone chips, they are usually absorbed. Amputation is at times indicated (Brunschwig<sup>13</sup>).

#### ANGIOMA

Central angioma of bone is a relatively rare tumor. The symptoms are similar to those of all primary bone tumors. The growth arises usually near the epiphyseal ends of the long bone, causing bone destruction and distention of the cortex. The radiograph closely resembles that of giant-cell tumor, but the trabeculae are usually more marked, giving a soap-bubble appearance. The treatment is the same as that of giant-cell tumor.

#### METASTATIC TUMORS

The possibility of a bone tumor's being a metastasis of a malignant growth arising elsewhere in the body should always be considered. Any malignant tumor may form bone metastases, although this is commoner in some forms than in others. In children, adrenocortical tumors often metastasize to the bone and the radiograph cannot be distinguished from that of osteogenic sarcoma. In adults, cancers of the breast, prostate and thyroid and hypernephroma are the commoner ma-

lignant tumors forming bone metastases. These may be either osteolytic or osteoblastic. Carcinoma of the thyroid usually metastasizes to the skull, ribs or vertebrae, while cancer of the breast may give either form of metastasis, in any bone of the body.

One should always consider the possibility of an apparent bone tumor's being a manifestation of a generalized metabolic disease, such as osteitis fibrosa cystica or Paget's disease.

#### PAROSTEAL FIBROSARCOMA

This tumor arises in the outer layers of the periosteum and involves the bone secondarily. It is somewhat less malignant than true osteogenic sarcoma and may be of neurogenic origin (Hodges, Phemister and Brunschwig<sup>14</sup>).

205 Beacon Street.

after three days of incubation. Non-pathogenic coagulase-negative strains of staphylococci characteristically grow quite slowly, hence it was my belief that this patient was suffering from an infection with a relatively avirulent strain of staphylococcus, as a result of a breakdown of the normal bactericidal defense mechanism that was occasioned by some serious underlying disease. She received no sulfanilamide at any time as the sulfanilamide compounds have not as yet been demonstrated to be effective in staphylococcal infections.

DR. RICHARD B. KING: At the time of the first admission it was apparent that she had agranulocytosis. She had a tremendous amount of treatment—40 cc of Pentnucleotide and 6 cc of liver extract daily, and so forth.

In relation to the last illness it is true that she developed a middle ear sufficient to warrant Dr. Reynolds's calling in an ear man to see her, the red eardrum and the earache subsided in twenty-four hours.

#### CLINICAL DIAGNOSIS

Acute yellow atrophy

#### DR. SHORT'S DIAGNOSES

Septicemia, *Staphylococcus aureus*  
Pylephlebitis  
Multiple liver abscesses

#### ANATOMICAL DIAGNOSES

Septicemia, *Staphylococcus aureus*  
Multiple abscesses of lungs and kidneys  
Acute glomerulonephritis  
Acute hepatitis  
Icterus  
Ascites  
Gastric erosions, acute, multiple

#### PATHOLOGICAL DISCUSSION

DR. MALLORY: The autopsy showed an extremely large liver extending 8 cm below the costal margin, almost to the umbilicus. It weighed 2800 gm. It was slightly greenish in color and quite normal in consistence, and outside of some obvious bile stasis we could not be sure anything was wrong with it. The lungs showed scattered abscesses, as also did the kidneys. The rest of the gross examination was essentially negative.

The findings on microscopic examination proved of interest because in the kidneys, in addition to the scattered abscesses, we found a typical, acute, diffuse glomerulonephritis of a very severe grade. Glomerulonephritis is not a recognized consequence of *Staphylococcus aureus* infection, and

that raises the question as to whether there was some other additional infection we never discovered. Our postmortem blood cultures and individual cultures from several of the abscesses, however, contained staphylococci and nothing else.

The liver showed a diffuse degenerative change of moderate intensity, the cells were swollen and vacuolated and contained bile pigment, but there was no actual necrosis of the liver cells. There were no abscesses in the liver, and nothing was found in the portal veins. We did not find the portal of entry of infection.

DR. JONES: That represents really a toxic jaundice?

DR. MALLORY: To what extent it was hemolytic or to what extent dependent on hepatic insufficiency is hard to say, possibly there was a combination of the two factors. The whole picture, including the nephritis, is not rare with streptococcal infection, but I cannot remember ever having seen it before with a staphylococcus.

DR. RICHARD J. CLARK: Is there any possibility that in a sensitive person there would be a toxic reaction of the liver or kidneys to the material which was injected to thrombose the veins?

DR. MALLORY: I cannot imagine a chemical substance which would produce glomerulonephritis—a toxic nephrosis, perhaps, but never a glomerulonephritis. I think we have to assume it is on an infectious basis.

DR. J. H. MEANS: In respect to the nephritis, it might be worth mentioning that a year or two ago we had a woman who, very shortly after an injection of quinine and urea of this sort, went into a picture of acute renal insufficiency—a very extraordinary case. She recovered after a time.

DR. MALLORY: That is an interesting observation.

DR. LYONS: Is there any reason to believe that the virulence tests we are doing for staphylococcus were at fault in this case?

DR. MALLORY: I am forced to believe that the organism in this instance was a fully virulent one.

#### CASE 25152

##### PRESENTATION OF CASE

A forty-eight-year-old Irish housewife was admitted complaining of vomiting.

Six years before admission the patient was told that her sclerae were yellow and that she should have gall-bladder studies. She had no other symptoms and further study was not done. Two years later she complained of paroxysmal epistaxes, especially with attacks of coryza. At this time her

now well established, and it is probably a phenomenon of hypersensitivity. It is interesting that there has been apparently a lessened incidence in the United States since this was known, and also in this hospital. Is that not so, Dr Mallory?

DR. TRACY B MALLORY: Very decidedly.

DR. SHORT: In Denmark in the past few years since the importation of amidopyrin has been prohibited, there have been no cases.

She had plenty of granulocytes on her last admission, so I can see no connection of this illness with the cause of death. I am also unable to connect the bladder lesion with the final illness, since there was no evidence of recurrence and no urinary symptoms.

We can now turn to the fatal illness. The picture was that of jaundice with sepsis, presumably due to *Staphylococcus aureus*. Only one other possibility occurred to me. That is acute liver necrosis, perhaps precipitated by the infection and perhaps on a previously damaged liver. However, there is no past history of jaundice and no history of taking any liver poisons. The liver is said to have been small on physical examination, but we know that such measurements are notoriously inaccurate. I can see no way of ruling out this diagnosis, but I do not believe I shall make it in the face of more positive evidence. We shall admit then that the patient had a generalized, fulminating staphylococcal infection, leading to death in less than two weeks. The next questions concern the organs involved and the source of the infection. We have already stated that, in view of the jaundice, the liver was involved, probably with multiple small abscesses. The negative chest plate and the absence of cough and sputum fairly well rule out pulmonary involvement, although it would be unusual not to have abscesses in the lungs in a generalized staphylococcal infection leading to death. There were no cardiac murmurs and no other signs pointing to any other location of the abscesses.

Now as to the source, she had a sore throat which could have been a portal of entry, she also had pain in the left side of the face and over the ear, which respectively suggest sinus and middle-ear infections, both fairly common sources. However, there was no further development there and examination of the ears was negative. In reading over the history I was interested in learning of the injection treatment of the hemorrhoids three days before the onset. I shall propose that as a possible source of infection, which started in the hemorrhoidal veins, led to portal involvement and finally resulted in a suppurative pylephlebitis with a staphylococcal septicemia. Such

cases have been described as a rare complication of sepsis in and around the rectum and following operations there. The course was more rapid than would be expected in ordinary pylephlebitis following appendicitis, and the liver was not enlarged. However, I am willing to venture this as my diagnosis—a staphylococcal septicemia with a suppurative pylephlebitis and multiple abscesses of the liver from infection of the portal system starting in a hemorrhoidal vein.

DR. TRACY B MALLORY: Until the positive blood cultures were reported in this case I am sure it was a good deal more of a puzzle than it is now. Perhaps Dr Jones would like to say a word.

DR. CHESTER M JONES: When I first saw this patient with Dr George P Reynolds and Dr Champ Lyons, there was no doubt about the intensity of the jaundice and we had a record, if I remember correctly, of one throat culture which was positive for staphylococci but not for streptococci. It was a question of whether there was any significance at all in the throat culture at that time. Throughout the patient's entire stay in the hospital it was impossible to demonstrate accurately the size of the liver. It seemed to me, however, that the liver was definitely small. Dr Short is right in stating that it is dangerous to say the liver is large or small, but there was moderate distention and the lower border of dullness was well above the costal margin. At the time it seemed as if there was acute hepatic insufficiency, and we had to treat it as such until we obtained more evidence. I believe that there was acute hepatic damage, cause unknown. At no time was it possible for me to think that the liver was enlarged, which is interesting in view of the post mortem findings. Several of us tried to outline the liver as carefully as we could.

Another point, which I think is of some interest, was the sustained high temperature. With acute yellow atrophy at times there is fever, but it is not as sustained or as high as this was. I am surprised it was not a picket-fence temperature.

DR. CHAMP LYONS: I was asked for an opinion as to the advisability of sulfanilamide therapy in this patient. There was no positive cultural diagnosis of hemolytic streptococcus, and I withheld sulfanilamide until such time as the culture was returned. The throat culture contained a large number of staphylococci, but these were coagulase negative when tested in human plasma. Those of us who are working with the staphylococci have come to attach a good deal of significance to the coagulase test as a test of virulence. The blood culture was positive for staphylococcus only.

disagree with what appears in the text—a high diaphragm with some compression of the lungs and not a large heart but one that is displaced by the diaphragm. There is tortuosity of the aorta which may be due to the high position of the heart. The shadow of the liver seems small. However, when the abdomen is full of fluid the liver floats up, you may get it in a different plane and in that way it seems small. I should think the only thing you could be certain about is that she had fluid in the abdomen.

DR. STEWART: Have you any comment to make about the displacement of the stomach to the right?

DR. HOLMES: If it was displaced to the right it would suggest that the liver was small or that there was an enlarged spleen on the other side pushing it over. However, I should not be at all certain that it was displaced.

DR. STEWART: Do any medical men want to comment on these electrocardiographic findings?

DR. WILLIAM B. BREED: They do not mean anything.

DR. STEWART: In this case I have been puzzled as to how to put the various findings together in one plausible diagnosis. There are a number of leads in the first part of the history that do not seem to be borne out subsequently. She had had hypertension, 240 systolic, in the past, while her blood pressure was 138 systolic, 75 diastolic, in the hospital. What was formerly taken to be enlarged thyroid gland was not noted in physical examination here, and there is no note as to enlargement or increase in density of the thyroid mass. Furthermore, glycosuria had been noted in the past, while the urine seemed to be free of sugar at every examination in the hospital. None of these apparent leads develop far enough to point anywhere in particular. The major problem seems to involve the explanation of the extensive edema and ascites with coincident obstructive jaundice. It is worth noting in passing that the physical signs in this case are rather like those we see in constrictive pericarditis, that is, she was said to have distention of the neck veins although in what portion we do not know. She had extensive ascites and apparently enlargement of the liver. There was hydrothorax without any significant amount of edema of the lungs, and that probably is an important point in discussing the diagnostic possibilities. Furthermore, but few abnormalities were noted in the examination of the heart, which is often true in cases of constrictive pericarditis. However, there are certainly not enough data to make that diagnosis here. She had a rather small pulse pressure. We have no information as to limitation

of extent of cardiac pulsation as determined by fluoroscopic examination. It is interesting that she apparently had dyspnea on exertion without orthopnea—that is frequently true in cases of constrictive pericarditis.

It seems to me that primary nephritis can be excluded as a cause for the extensive edema and ascites in this case. To be sure, there was some albumin in the urine, but there is no record of any cytological findings in the urine and the concentrating power was good. The question of whether the change from a hypertensive state to a condition of fairly normal range of blood pressure is significant in the present illness I cannot settle. In view of the electrocardiographic findings and physical examination I am inclined to think that she did not have any primary cardiac disease which might lead to the extensive edema and ascites. We come to considering the sudden development or intensification of the ascites. According to the story the edema of the extremities developed some months before the patient noted enlargement of the abdomen. Of course that is not necessarily accurate information, in that she may have developed and not noticed ascites during the same period of time. However, it does appear to be definite that two weeks before admission there was a rapid enlargement of the abdomen.

I do not believe that primary peritonitis or carcinomatosis of the peritoneum could give this picture. The fluid withdrawn amounted to 6000 cc and had all the characteristics of a transudate. There was no blood in it. No tumor cells were found, which means very little so far as making a diagnosis of widespread carcinoma of the peritoneum is concerned. We come then to consideration of the possibility of cirrhosis. There is a story going back over six years during which time the patient had recurring bouts of mild jaundice, with impairment of her general health. The jaundice apparently was not obstructive, and was of mild degree. Certainly bile was coming through into the gastrointestinal tract. The question of whether she had cirrhosis on the basis of chronic and intermittent obstruction of the common duct, as from stone, has to be considered. It seems to me there is not very much on which to make a diagnosis of biliary cirrhosis in this case. There was little if any abdominal pain with the attacks of jaundice, and apparently little or no fever, certainly no definite chill. If she had biliary cirrhosis with stone one might suppose that the picture was changing with the development of carcinoma of the gall bladder and obstruction to the portal vein. However, I think that is not a very likely diagnosis. Could she have had cirrhosis of the liver of the toxic

blood pressure was found to be 240 systolic. There was a swelling in her neck said to be the thyroid gland. Three years before entry she noticed weakness in the knees while walking, and she restricted her activities. She had slight swelling of the ankles, relieved by rest. One year before admission she was told that she had sugar in her urine and was given pills. Since she was eating very little a diet was not prescribed. She had had intermittent episodes of yellow sclerae since the onset, there had been no pain. Seven months prior to entry she noted soreness of the ribs on both sides on rising from bed, and a numb feeling from the waist to the knees, which in several days extended to her legs and feet. She also began to have nausea, and vomited yellow bitter fluid and food eaten the night before. Her urine became dark but soon returned to normal color. The swelling of her ankles increased and two months later reached the point where she could not put on her shoes. Four months before entry she was put on a diet restricted to fruits and fluids. She could not take cream because it precipitated vomiting. She began to lose weight, and had lost 35 pounds during the seven months before admission. Two months later she noticed dyspnea on exertion, but no orthopnea. Her skin became slightly yellow. From this time on she remained in bed. Two weeks before entry her abdomen began to swell rapidly. The urine became very dark, the stools were gray and her jaundice deepened, though it faded slightly during the week preceding entry.

There had been no pregnancies. During the previous six years her catamenia had been irregular and had ceased eight months before admission, this being followed by severe hot flashes. She repeatedly and emphatically denied the use of alcoholic beverages.

Physical examination showed a well-developed, undernourished woman with rapid shallow respirations. The skin was sallow and slightly icteric, the sclerae decidedly icteric. There was pitting edema below the costal margin. The neck veins were dilated, but there was no cyanosis. Examination of the chest revealed some elevation of the diaphragm and a few fine rales over the right base. The heart was negative. The blood pressure was 138 systolic, 75 diastolic. The abdomen was tense, with small dilated veins over both sides. By percussion the upper border of liver dullness was at the fourth rib, the lower border 5 cm below the right costal margin. Palpation was practically impossible. Pelvic and rectal examinations were both negative. There was pitting edema of both legs, and deep tenderness

over the lumbar spine. There were no definite neurological findings.

The temperature was 100°F, the pulse 95, and the respirations 22.

Examination of the urine showed a specific gravity of 1.034, a very slight trace of albumin and a trace of bile. The blood showed a red-cell count of 2,670,000 with 80 per cent hemoglobin, and a white-cell count of 22,100 with 83 per cent polymorphonuclears. The blood smear showed no abnormal cells. The serum nonprotein nitrogen was 29 mg per 100 cc, the protein 6.2 gm., and the van den Bergh 10.80 mg., diphasic. A blood Hinton test was negative. The stools were brown, and repeated examinations were guaiac negative. A Takata-Ara test was positive.

X-ray films of the chest showed a high diaphragm with a small amount of fluid in both pleural cavities. The heart was in transverse position and possibly slightly enlarged. The aorta was tortuous. A flat abdominal film showed the psoas shadows poorly outlined. There was no evidence of enlargement of the liver, rather it seemed smaller than normal. The spleen was not visible. The bones showed no abnormality. A gastrointestinal series showed the stomach displaced to the right. There were no varices. The remainder of the gastrointestinal tract was normal.

On the second hospital day an abdominal paracentesis yielded 6000 cc. of clear yellow fluid, with a specific gravity of 1.010 and 150 cells per cubic millimeter. No tumor cells were seen. After removal of the fluid a mass was palpable in the mid-epigastrium, which by one observer was thought to be rough and nodular, by another smooth. It extended about a handbreadth below the xiphoid process and was thought to be the left lobe of the liver. An electrocardiogram on the second day showed a low T<sub>1</sub>, a diphasic T<sub>2</sub> and an inverted T<sub>3</sub>. The P-R interval was 0.13 seconds, and the rhythm normal. On the ninth hospital day the patient was given Salyrgan. The following day there was considerable vomiting, she became quite dehydrated, and the temperature rose to 103°F, rectally. Two days later the serum nonprotein nitrogen was 53 mg per 100 cc, the chlorides 98.6 milliequivalents. The temperature was 103.5°F. Her pulse had risen to 176, the respirations to 35. She rapidly failed and died the following day, twelve days after admission.

#### DIFFERENTIAL DIAGNOSIS

DR JOHN D STEWART May we see the x-rays?

DR GEORGE W HOLMES The high position of the diaphragm makes any interpretation of the chest difficult, but I do not see any reason to

disagree with what appears in the text—a high diaphragm with some compression of the lungs and not a large heart but one that is displaced by the diaphragm. There is tortuosity of the aorta which may be due to the high position of the heart. The shadow of the liver seems small. However, when the abdomen is full of fluid the liver floats up, you may get it in a different plane and in that way it seems small. I should think the only thing you could be certain about is that she had fluid in the abdomen.

DR. STEWART: Have you any comment to make about the displacement of the stomach to the right?

DR. HOLMES: If it was displaced to the right it would suggest that the liver was small or that there was an enlarged spleen on the other side pushing it over. However, I should not be at all certain that it was displaced.

DR. STEWART: Do any medical men want to comment on these electrocardiographic findings?

DR. WILLIAM B. BREED: They do not mean anything.

DR. STEWART: In this case I have been puzzled as to how to put the various findings together in one plausible diagnosis. There are a number of leads in the first part of the history that do not seem to be borne out subsequently. She had had hypertension, 240 systolic, in the past, while her blood pressure was 138 systolic, 75 diastolic, in the hospital. What was formerly taken to be enlarged thyroid gland was not noted in physical examination here, and there is no note as to enlargement or increase in density of the thyroid mass. Furthermore, glycosuria had been noted in the past, while the urine seemed to be free of sugar at every examination in the hospital. None of these apparent leads develop far enough to point anywhere in particular. The major problem seems to involve the explanation of the extensive edema and ascites with coincident obstructive jaundice. It is worth noting in passing that the physical signs in this case are rather like those we see in constrictive pericarditis, that is, she was said to have distention of the neck veins although in what portion we do not know. She had extensive ascites and apparently enlargement of the liver. There was hydrothorax without any significant amount of edema of the lungs, and that probably is an important point in discussing the diagnostic possibilities. Furthermore, but few abnormalities were noted in the examination of the heart, which is often true in cases of constrictive pericarditis. However, there are certainly not enough data to make that diagnosis here. She had a rather small pulse pressure. We have no information as to lim-

itation of extent of cardiac pulsation as determined by fluoroscopic examination. It is interesting that she apparently had dyspnea on exertion without orthopnea—that is frequently true in cases of constrictive pericarditis.

It seems to me that primary nephritis can be excluded as a cause for the extensive edema and ascites in this case. To be sure, there was some albumin in the urine, but there is no record of any cytological findings in the urine and the concentrating power was good. The question of whether the change from a hypertensive state to a condition of fairly normal range of blood pressure is significant in the present illness I cannot settle. In view of the electrocardiographic findings and physical examination I am inclined to think that she did not have any primary cardiac disease which might lead to the extensive edema and ascites. We come to considering the sudden development or intensification of the ascites. According to the story the edema of the extremities developed some months before the patient noted enlargement of the abdomen. Of course that is not necessarily accurate information, in that she may have developed and not noticed ascites during the same period of time. However, it does appear to be definite that two weeks before admission there was a rapid enlargement of the abdomen.

I do not believe that primary peritonitis or carcinomatosis of the peritoneum could give this picture. The fluid withdrawn amounted to 6000 cc and had all the characteristics of a transudate. There was no blood in it. No tumor cells were found, which means very little so far as making a diagnosis of widespread carcinoma of the peritoneum is concerned. We come then to consideration of the possibility of cirrhosis. There is a story going back over six years during which time the patient had recurring bouts of mild jaundice, with impairment of her general health. The jaundice apparently was not obstructive, and was of mild degree. Certainly bile was coming through into the gastrointestinal tract. The question of whether she had cirrhosis on the basis of chronic and intermittent obstruction of the common duct, as from stone, has to be considered. It seems to me there is not very much on which to make a diagnosis of biliary cirrhosis in this case. There was little if any abdominal pain with the attacks of jaundice, and apparently little or no fever, certainly no definite chill. If she had biliary cirrhosis with stone one might suppose that the picture was changing with the development of carcinoma of the gall bladder and obstruction to the portal vein. However, I think that is not a very likely diagnosis. Could she have had cirrhosis of the liver of the toxic

type, or so-called portal cirrhosis? It seems to me that that is a possibility. It would explain the digestive disturbances and the mild jaundice which she had had from time to time. It might lead to what we take to be an enlarged liver, and it might give her the ascites and even the peripheral edema. However, there are a number of things lacking to make it a highly plausible diagnosis. We have no evidence of the development of collateral circulation, although there is a note of small dilated veins on the lateral abdominal wall. She had no esophageal varices, and her stools were guaiac negative. If she had portal cirrhosis, what produced the sudden change in the picture? It is a rather far cry, but I do not see why, having cirrhosis, she might not have developed secondarily a carcinoma which produced pressure on the portal vein and rapidly progressing ascites.

Could she have been having recurring mild bouts of hepatitis with subsequent development of acute yellow atrophy? That does not seem to me to be the most plausible diagnosis. Apparently she had some obstruction to the flow of bile, for immediately before entry the stools were clay colored. That probably is an important point, if the observation is correct.

I can do no better than say that I believe this woman had cirrhosis of the liver and that she probably had carcinoma in addition, perhaps developing in the liver as a primary lesion.

DR. J. H. MEANS: I was in charge of the service when this patient was on it, and there were several differences of opinion about the diagnosis. Two of these concerned the size of the liver and its consistence. The x-ray people told us that the liver seemed to be rather small, and yet we thought that we felt it and that it was definitely enlarged. The senior house officer was absolutely certain that the liver was grossly irregular and contained hard nodules and that therefore she had some form of malignant disease in the liver. I personally thought the liver was smooth, so we asked Dr. Benedict to have a look at it to settle this point, if he could, but his examination was postponed for some unavoidable reason, and by the time he could do it she had developed fever and was too sick. She died, I am sure, of a terminal infection, but I think she had cirrhosis of the liver with hepatic insufficiency. But as I said, the senior house officer thought she had malignant disease in the liver, and the junior signed the case off, because of that opinion, as one of metastatic carcinoma of the liver, possibly from the pancreas, with a questionable diagnosis of hepatoma.

Among other diagnoses that Dr. Stewart has mentioned, I think it is interesting to note that

the house officer who made the admission summary included the possibility of cirrhosis, with acute hepatitis. I should like to have that diagnosis of Dr. Hawes made a matter of record.

There are two points brought up by Dr. Stewart on which I might comment. We found no evidence of Graves's disease. In regard to glycosuria, hemachromatosis was considered, but she had no glycosuria in the hospital except after receiving intravenous glucose.

DR. CHESTER M. JONES: It seems to me that jaundice of six years' duration must be included as part of the picture, and I should agree with Dr. Stewart and Dr. Means that she must have had chronic intrahepatic disease that could be labeled cirrhosis. That is not enough to explain her death and terminal picture. I am in favor of superimposed cancer.

DR. TRACY B. MALLORY: Do you think in these cirrhotic cases we are missing information by not fractionating the serum protein? One can have a normal total protein level but nevertheless an albumin so low that ascites and edema may develop without mechanical obstruction.

DR. JONES: On the wards I see very few cases of cirrhosis with ascites which do not have an inverted albumin-globulin ratio, although some have normal serum protein values. No doubt we should fractionate the protein. Another thing that might have given some confirmatory evidence is a dye test. If she had shown abnormal dye retention we should have had more evidence of diffuse liver involvement.

DR. MEANS: There was a positive Takata Ara test.

DR. JONES: As a rule that is not so significant as the dye test.

#### CLINICAL DIAGNOSES

Metastatic carcinoma of liver, probably from pancreas  
Hepatoma?

#### DR. STEWART'S DIAGNOSES

Portal cirrhosis of liver  
Hepatoma

#### ANATOMICAL DIAGNOSES

Acute alcoholic cirrhosis of the liver  
Septicemia, *Streptococcus hemolyticus*  
Ascites  
Icterus  
Arteriosclerosis

#### PATHOLOGICAL DISCUSSION

DR. MALLORY: The autopsy showed an enlarged, absolutely smooth liver. The spleen was small,

weighing only 100 gm, so I do not think there could have been a significant degree of portal obstruction. We have to fall back on the possibility of a very low serum albumin as an explanation of the ascites and edema. The liver, although smooth, was firm and very tough when one attempted to section it. On microscopic examination it is slightly but diffusely cirrhotic, with a very marked degree of fatty vacuolization and also in one cell out of every ten the characteristic hyaline degeneration that one sees in acute alcoholic injury to the liver. Subsequent to the autopsy we received some confirmatory evidence of that. A medical student who had known the patient gave us the information that she was a notorious alcoholic. In this city, I think it is fair to say that acute alcoholism is the commonest cause of fulminating acute liver insufficiency. We see very few cases here but they see a considerable number at the Boston City Hospital at all times.

DR. JONES: Mostly gin?

DR. MALLORY: Mostly alcohol purchased in drugstores and diluted to variable extents, it at all. This is, I believe, the only state in the country in which it is possible to buy straight alcohol without prescription at the drugstores.

DR. MEANS: As I recall, you did not think there was much cirrhosis at the time you did the autopsy.

DR. MALLORY: At the time I showed you the organ I had not yet attempted to cut it. It was

definitely cirrhotic but not granular. It was characteristic of the early stage of alcoholic cirrhosis.

DR. STEWART: Was there very much fluid in the pleural cavity?

DR. MALLORY: None.

DR. JONES: It seems to me one point might be mentioned which involves a fair number of cases that we see here. A good many of our cases of hepatic insufficiency in acute as well as chronic alcoholism do have really big livers. In other words we are recognizing them earlier than we used to, and we see the intermediate stage before they develop small livers. These are the patients that do best if you catch them in time and eliminate the alcohol.

DR. HOLMES: Did she have any tortuosity of the aorta?

DR. MALLORY: Her heart weighed 350 gm, which was evidence of very slight hypertrophy, and the aorta showed only very slight atheromatous changes.

DR. MEANS: She had a terminal streptococcal septicemia?

DR. MALLORY: Yes, although she had enough severe and acute liver damage to have died primarily of the liver insufficiency.

DR. MEANS: As I recall, she was running only slight fever for several days, and we were not aware of the urgency of the situation until she developed a high fever and died.

type, or so-called portal cirrhosis? It seems to me that that is a possibility. It would explain the digestive disturbances and the mild jaundice which she had had from time to time. It might lead to what we take to be an enlarged liver, and it might give her the ascites and even the peripheral edema. Slight though this tendency may be, there have been enough distinguished examples in the past to make one hesitate to place the least check on such a beneficent interchange of teachers. If citizenship is required for the ordinary practitioner, due provision in the law should be made for the teacher.

Whatever may be the motive behind this particular bill, there is distinct merit in the idea that the physician should be identified politically, as well as professionally and socially, with the community which he serves, and that whatever form the expression of his loyalty may take it should have the broadest basis possible. Will a law accomplish anything in this direction? The sometimes startling ineffectiveness of the statutes in assisting us to control our emotional reactions should also be noted in this connection.

#### THE CARE OF MENTAL DISEASE IN MASSACHUSETTS

THERE has recently been issued the report of the Special Commission on Mental Diseases based on a year's study of the state institutions and the organization of the Massachusetts Department of Mental Health. The report, on the whole, is excellent, and of particular value is the survey made by Dr Samuel W. Hamilton, of New York, on mental institutions in Massachusetts. Such an impartial survey has long been needed, and it is with gratification that one notes how relatively little there was to criticize about the care of the mentally ill in this state. Dr Hamilton called attention to the fine medical organization which was handling the problem sympathetically and intelligently and doing a vast amount of service to the Commonwealth. In his opinion the present structure of the department as set up in 1958 should be given a thorough trial. He pointed out, nevertheless, that the most effective organization is one headed not by a commissioner with associate commissioners but by a council on mental health, the councilors being persons expert in various fields related to the work of the department. This was his general recommendation, although he suggested a good many relatively minor

changes which would improve the system as a whole. His report should be given the most careful consideration by the Legislature.

In addition to Dr Hamilton's recommendations, two other important problems should be emphasized. One concerns the Boston Psychopathic Hospital and its future, and the other the recommendation for a hospital for the criminally insane. The commission had several thoughts concerning the Boston Psychopathic Hospital. Its first was complete abolition of the hospital and the transfer of the several associated departments to some other hospital center. Patients with acute undiagnosed mental disease would, under these circumstances, be handled in several of the city hospitals, or there might be established a psychiatric service in one of the general hospitals in Boston. If this took place, the building now used might well serve as an office building for several of the state departments. As an alternative to this plan it was suggested that the Boston Psychopathic Hospital increase its bed capacity, that more provision be made for continued hospitalization, particularly for thirty-five-day court observation, and that its medical personnel be drawn, in large part at least, from state-hospital groups.

The suggestion of abandoning the Boston Psychopathic Hospital, which has been such a pioneer in this country in the work of classifying and distributing patients supposed to have mental disease, comes as a distinct shock to the medical profession. There is little to justify such a radical step. The hospital has served its purpose admirably in the past and with a few changes could continue to do so. What is needed most is increased bed capacity and more space for research laboratories. To abolish the close connection with the Harvard Medical School would be catastrophic, for the hospital has become one of the great teaching centers of this country. It is unfortunate, however, that it has not served as a teaching center for men who later enter the Massachusetts state hospitals. An effort should be made to give each new medical officer in a state hospital at least six months' training at the Boston Psychopathic Hospital. Plans, moreover, should be made for all state medical officers now serving

## SHOULD PHYSICIANS BE CITIZENS?

THIS question has been asked frequently of late when, sometimes in dramatic fashion, the desire and need of refugees to pursue their lifelong vocation in this the country of their refuge have become known. It is not a new problem, as the statutes of several states show. In those commonwealths no alien can be registered for the practice of medicine. But there is a larger problem, involving not aliens in the political sense, but native-born persons who shirk the responsibility of citizenship. They are called citizens, but too many physicians absorbed in the practice of medicine—and it is indeed an absorbing vocation—have turned a deaf ear to the calls on their time and strength which the highest welfare of the state demands. They scorn "politics" as unworthy, if not of an

honest man, at least of a member of the medical profession. But at one time when the state was circumscribed within the confines of the city, politics had to do with the welfare of the state. To the Greek, who gave us the word "politics," the man who failed in his duty to the state was no citizen.

The lawyer must be a citizen for he is an officer of the court of law which is a part of the government, and the moral responsibility of the physician is no less than that of the lawyer. By the very nature of his work he enters, more deeply perhaps than the member of any other profession, into the life of his community, and consciously or unconsciously molds it, for good or for ill, far beyond his influence in ministering to purely physical needs. Should not everyone who holds such power be politically sympathetic with those fundamental ideas for which representative government stands?

Even if one is at first convinced by this line of argument several questions arise, and the first one that is asked about such legislation as is proposed in House Bill 1407, now before the Committee on Public Health of the Legislature, is, What harm results under the present law? Obvious harm there may not be, but in these days of rampant and often unwise, if not insane, nationalism, it is well to remember that there is such a thing as wise nationalism, without which no wise internationalism or world peace is possible. The practical question is whether the requirement of citizenship for every physician will enhance his sense of proper loyalty to the fundamental political ideals of this country.

It is to be kept in mind also that the physician is not an itinerant and that in general the more fully he identifies himself with the community in which he lives, the greater is his loyalty and the better he serves the community. But there is a possible disadvantage. While the physician is not itinerant, the teacher may be, and with the development of medical education in connection with universities, there has been a tendency to develop visiting and exchange professorships, and sometimes a foreigner is called to a teaching position.

Slight though this tendency may be, there have been enough distinguished examples in the past to make one hesitate to place the least check on such a beneficent interchange of teachers. If citizenship is required for the ordinary practitioner, due provision in the law should be made for the teacher.

Whatever may be the motive behind this particular bill, there is distinct merit in the idea that the physician should be identified politically, as well as professionally and socially, with the community which he serves, and that whatever form the expression of his loyalty may take it should have the broadest basis possible. Will a law accomplish anything in this direction? The sometimes startling ineffectiveness of the statutes in assisting us to control our emotional reactions should also be noted in this connection.

#### THE CARE OF MENTAL DISEASE IN MASSACHUSETTS

THERE has recently been issued the report of the Special Commission on Mental Diseases based on a year's study of the state institutions and the organization of the Massachusetts Department of Mental Health. The report, on the whole, is excellent, and of particular value is the survey made by Dr Samuel W Hamilton, of New York, on mental institutions in Massachusetts. Such an impartial survey has long been needed, and it is with gratification that one notes how relatively little there was to criticize about the care of the mentally ill in this state. Dr Hamilton called attention to the fine medical organization which was handling the problem sympathetically and intelligently and doing a vast amount of service to the Commonwealth. In his opinion the present structure of the department as set up in 1938 should be given a thorough trial. He pointed out, nevertheless, that the most effective organization is one headed not by a commissioner with associate commissioners but by a council on mental health, the councilors being persons expert in various fields related to the work of the department. This was his general recommendation, although he suggested a good many relatively minor

changes which would improve the system as a whole. His report should be given the most careful consideration by the Legislature.

In addition to Dr Hamilton's recommendations, two other important problems should be emphasized. One concerns the Boston Psychopathic Hospital and its future, and the other the recommendation for a hospital for the criminally insane. The commission had several thoughts concerning the Boston Psychopathic Hospital. Its first was complete abolition of the hospital and the transfer of the several associated departments to some other hospital center. Patients with acute undiagnosed mental disease would, under these circumstances, be handled in several of the city hospitals, or there might be established a psychiatric service in one of the general hospitals in Boston. If this took place, the building now used might well serve as an office building for several of the state departments. As an alternative to this plan it was suggested that the Boston Psychopathic Hospital increase its bed capacity, that more provision be made for continued hospitalization, particularly for thirty-five-day court observation, and that its medical personnel be drawn, in large part at least, from state-hospital groups.

The suggestion of abandoning the Boston Psychopathic Hospital, which has been such a pioneer in this country in the work of classifying and distributing patients supposed to have mental disease, comes as a distinct shock to the medical profession. There is little to justify such a radical step. The hospital has served its purpose admirably in the past and with a few changes could continue to do so. What is needed most is increased bed capacity and more space for research laboratories. To abolish the close connection with the Harvard Medical School would be catastrophic, for the hospital has become one of the great teaching centers of this country. It is unfortunate, however, that it has not served as a teaching center for men who later enter the Massachusetts state hospitals. An effort should be made to give each new medical officer in a state hospital at least six months' training at the Boston Psychopathic Hospital. Plans, moreover, should be made for all state medical officers now serving

mental hospitals to spend at least a few months' time at the Boston Psychopathic Hospital every few years. There they would be inculcated with a spirit of research, which should serve a very useful purpose when they return to their individual state units. As a corollary to this, research should be more fostered in the state hospitals, and better laboratories and libraries provided. The state of the psychiatric libraries for professional use in our state institutions for mental disease is, in most cases, appalling. A few hundred old books and one or two journals are all that is available for the younger men, who most need the stimulus of constant reading. It is believed, therefore, that the Boston Psychopathic Hospital should be maintained as a unit in an expanded form.

The second problem, in regard to the care of the criminally insane in Massachusetts, is one that really needs little comment. For a number of years everyone adequately informed on the subject has recommended a special hospital for this group of patients, to be constructed on state land, presumably at Norfolk. This would replace the state hospital department at Bridgewater State Farm, where the care of the criminally insane is almost necessarily custodial and not medical.

### SECTION OF OBSTETRICS AND GYNECOLOGY\*

RAYMOND S. TITUS, M.D., *Secretary*  
330 Dartmouth Street  
Boston

#### POSTPARTUM HEMORRHAGE

Miss N., a twenty-one-year-old gravida I, entered the hospital on June 2, 1938, to await confinement. At this time she was approximately thirty-eight weeks pregnant.

The family history was irrelevant. The patient had had the usual childhood diseases but no serious operations. Catamenia began at thirteen, were regular with a twenty-eight-day cycle, and lasted four days without pain. Her last period was September 10, 1937, making her due for delivery June 17.

\*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

Examination on admission disclosed a small, fairly well-developed and nourished young woman. Her entire physical examination was negative. The lungs were clear and resonant, the heart was not enlarged, and there were no murmurs. The fundus lay two fingerbreadths below the xiphoid cartilage, the head was presenting and floating. The fetal heart was heard best in the right lower quadrant and had a rate of 137. Pelvic measurements were as follows: interspinous, 21.5 cm, intercrural, 25 cm, external conjugate, 19 cm. Urinalysis was negative, the blood Wassermann test and urethral and cervical smears were negative. Her prenatal course was normal, the blood pressure had never gone above 110 systolic, 70 diastolic, and she had had no toxic signs or symptoms.

Labor started at 10:45 p.m. on June 23 and in fifteen and a quarter hours the patient was fully dilated. There was no further progress in the next two hours and a half, and because of this, forceps delivery was entertained. The head was well in the pelvis and was in a partially rotated ODP position. A forceps was applied, and the baby delivered at 4:55 p.m. on June 24. The placenta and membranes were expressed intact, but the uterus failed to maintain good contraction and a very brisk hemorrhage occurred. An ampule of posterior pituitary extract was administered. The pulse rose precipitously to 160 per minute, its quality was thready and weak, and the patient was clammy and perspired freely. A second ampule of pituitary extract was administered, and the fundus judiciously massaged. Two ampules of ergot were then given, this was followed by a cessation of hemorrhage. Immediately after delivery an intravenous clysis of 700 cc. of 5 per cent glucose in saline solution had been administered. The patient was placed in Trendelenburg position, heat was applied by means of blankets, and a firm abdominal binder was placed over the lower abdomen. Four hours post partum the patient's pulse had dropped to 100 per minute, and her condition improved rapidly thereafter. On her return to bed she was given 1/6 gr. of morphine and a clysis of 500 cc. of 5 per cent glucose in saline solution. A course of Ergotone was given on the second postpartum day. The fundus remained well contracted, the flow was normal, and the patient was discharged on the fourteenth day after delivery. The blood hemoglobin on discharge was 68 per cent.

*Comment.* This case illustrates the commonest cause of moderate postpartum hemorrhage due to uterine inertia. As is so often the case, oxytocics will initiate uterine contraction without the need

of intrauterine exploration There is no mention made of blood grouping and matching, which should be a routine procedure Fortunately, this patient's condition improved without transfusion There is no evidence in the history of the case that in any way shows that this moderate hemorrhage could have been prevented, however, there is no record that the fundus was held any length of time after the initial bleeding Presumably, however, it was held until the periods of contraction were far longer than those of relaxation The use of a firm abdominal binder, as mentioned in this case, surely has no value in preventing relaxation of the uterus

### SPECIAL MEETING OF THE COUNCIL

A special meeting of the Council of the Massachusetts Medical Society will be held in John Ware Hall, Boston Medical Library, 8 Fenway, Boston, on Wednesday, April 26, at 10:00 a m

#### BUSINESS

Consideration of the report of the Committee on Public Relations on social legislation and insurance.

This will be an important meeting and full attendance is desired

ALEXANDER S BEGG, *Secretary*

Councilors are asked to sign one of the two attendance books before the meeting The Cotting Luncheon will be served immediately after the meeting

### LEGISLATIVE NOTE

The chiropractic bill, now before the Committee on Public Health, has been given a number, House Bill 2151

The people who favor this bill have been particularly active this year, and we strongly urge each member of the Society to write to his senator, his representative and members of the Committee on Public Health asking them to oppose it The hearing will be held at 10.30 a m., April 25, in the Gardner Auditorium Please come and bring your friends!

CHARLES C LUND, *Chairman*  
Committee on State and  
National Legislation

### MEDICAL POSTGRADUATE EXTENSION COURSES

The following sessions, given by the Massachusetts Medical Society in co-operation with the Massachusetts Department of Public Health, the United States Public Health Service and the Federal Children's Bureau, have been arranged for the week beginning April 17

#### BARNSTABLE

Sunday, April 23, at 4 00 p m., at the Cape Cod Hospital, Hyannis. Subject—Bright's Disease and Hypertension Evaluation of new therapy diagnosis. Instructor Robert S Palmer Donald E Higgins, *Chairman*

#### BERKSHIRE

Thursday, April 20, at 4.30 p m., at the House of Mercy Hospital, Pittsfield. Subject—The Indications and Contraindications for Removal of Tonsils and Adenoids. Instructor James M Baty Melvin H Walker, Jr, *Chairman*

#### FRANKLIN
